

2006 **PROCEEDINGS**

22nd Annual National Environmental Monitoring Conference

THE HEALTH, DEPTH, AND BREADTH OF THE ENVIRONMENTAL MONITORING INDUSTRY

Arlington, Virginia August 28 - 31, 2006

SPONSORED BY:

NEMC 2006 ORGANIZING COMMITTEE

Conference Co-Chairs

Lara Autry, USEPA Conference Chair Earl Hansen, ILI Program Chair Jerry Parr, INELA Conference Organizer

Program Committee

Benz, Robert	Environmental Express
Boline, Duane	Kansas Department of Health & Environment
Cassedy, Joan	ACIL
Crumbling, Deana	USEPA
DiRienzo, Robert	DataChem Laboratories
Kingston, Skip	Duquesne University
Grosser, Zoe	PerkinElmer LAS
Later, Doug	Dionex
Lipka, Doug	USEPA
MacLean, Fred	US Navy
Moore, Marlene	Advanced Systems
Mudambi, Anand	USEPA
Nagourney, Stuart	New Jersey DEP
Pozda, Oksana	USEPA
Solsky, Joe	US Army Corps of Engineers
Speis, David	Accutest Laboratories
Spence, Bill	Thermo Electron
Sturgeon, Shannon	USEPA
Venner, Brad	USEPA
Ward, Gary	Columbia Analytical
Whipple, Wayne	USEPA
Wyeth, Robert	Severn Trent Laboratories
Yang, Shen-yi	USEPA

TABLE OF CONTENTS

Monday, August 28, 2006

Special Session on Detection and Quantitation Limits

1	Clean Water Act Programs: Analytical Method Activities – Reding (presentation)	11
2	Estimating Detection Quantitation Limits – Burrows (abstract)	28
3	The ACIL Detection and Quantitation Limit Procedure – Burrows (presentation)	29
4	A Simple Procedure for Determination of Method Quantitation Limits – Mao (paper)	40
5	A Simple Procedure for Determination of Method Quantitation Limits – Mao (presentation)	52
6	Multi-Event Detection Limit Study – Carter, et al (abstract)	73
7	Report on a Multi-Event, Multi-Analyte, Multi-Method Detection Limit Study – Carter, et al (paper)	74
8	Report on a Multi-Analyte, Multi-Method Detection Limit Study – Carter, et al (presentation)	83
9	False-False Positives – Dechant (abstract)	99
10	Understanding False Positives and False-False Positives – Dechant (paper)	101

Tuesday, August 29, 2006

Plenary Session

11	The Health, Depth and Breath of Environmental Monitoring in the United States – A Commercial Laboratory Perspective – Wyeth (presentation)	110
12	The Environmental Monitoring Industry: Municipal Perspective – Pletl, et al (presentation)	124
13	Health, Depth, and Breadth of the Environmental Monitoring Industry – Boline (presentation)	136
14	Update on Activities Affecting the Industry – Parr (presentation)	147

Organic Methods

15	SPE Detection of Contaminants in Public Water – Hall (abstract)	182
16	Fast Automated SPE for the Detection and Analysis of a Wide Spectrum of Chemical Contaminants in Public Water Supplies and Process Waters – Hall (presentation)	183
17	Endocrine Disrupting Compounds in River Water – Borton, et al (abstract)	193
18	LC/MS/MS Analysis of 75 Endocrine Disrupting Compounds, Pharmaceuticals, and Personal Care Products in River Water – Borton, et al (presentation)	194
19	Haloacetic Acids by Ion Chromatography – Antonsen, et al (abstract)	215
20	Analysis of Haloacetic Acids and Bromate by IC-ESI-MS/MS – El Aribi (presentation)	216
21	Advances in Preparation and Analysis of Organic Compounds: Immobilized Liquid Extraction of Drinking or Waste Water as a New Sample Preparation Technique for GC/LC Analysis – Gullett, et al (abstract)	230
22	Immobilized Liquid Extraction™ of Drinking or Waste Water as a New Sample Preparation Technique for GC/LC Analysis – Wohleb, et al (paper)	231
23	Immobilized Liquid Extraction™ of Drinking or Waste Water as a New Sample Preparation Technique for GC/LC Analysis – Wohleb (presentation)	238
24	Accelerated Solvent Extraction (ASE [®]) as an Innovative Sample Preparation Technique for Conventional and Emerging Pollutants in Environmental Samples – Henderson, et al (abstract)	262
25	Accelerated Solvent Extraction (ASE [®]) as an Innovative Sample Preparation Technique for Conventional and Emerging Pollutants in Environmental Samples – Henderson, et al (presentation)	263

page

Chemical Speciation – As

26	Analzying Arsenic Species in Seafood – Chamberlain (abstract)	270
27	A Procedure for Extracting and Analyzing Arsenic Species in Seafood – Le, et al (presentation)	271
28	Arsenic Species Determination – Pohl and Slingsby (abstract)	282
29	Separation and Detection of Arsenic Species using Dual Selectivity IC-MS – Slingsby, et al (paper)	283
30	Determination of Five Arsenic Species Using Dual Ion Chromatography Coupled with Electrospray Ionization Mass Spectrometry – Slingsby, et al (presentation)	290
31	Identification, Characterization, and Quantitation of Species of Arsenic and Selenium by Hybrid Triple Quadrupole – QTRAP™ Mass Spectrometers – Ellis, et al (presentation)	303
32	Routine Arsenic Speciation Analysis by IC-ICP-MS? Are We There Yet? – Gerads and Gürleyük (abstract)	315
33	Routine Arsenic Speciation Analysis by IC-ICP-MS? Are We There Yet? – Gerads and Gürleyük (presentation)	316
34	Direct Injection of Water Samples to Analyze Pesticides at Concentration of 0.1μ G/L Using LC/MS/MS – Besa, et al (abstract)	338
35	A Brief Overview of the Role of Speciation Analysis for Environmental Analysis – Sperling (presentation)	339

Managing Uncertainty

36	Triad: Why Isn't It Used More? – Nagourney (abstract)	358
37	Triad: Why Isn't It Used More? – Nagourney (presentation)	359
38	Estimation of Uncertainty Based on QC Data: Nested Hierarchical Approach – Ingersoll (paper)	367
39	Estimation of Analytical Measurement Uncertainty – Ingersoll (presentation)	372
40	Data Usability: Making a Decision with Variable Data – Moore (paper)	390
41	Data Usability: Making a Decision with Variable Data – Moore (presentation)	394
42	WEB-EDMS System – Garrison and Young (abstract)	403
43	Web-based Environmental Data Management System – A System for Real Time Environmental Data Management and Risk Assessment – Garrison and Young (presentation)	404
44	Triad to Increase Certainty in Remediation Design – Mack (abstract)	419
45	Triad and Remediation Design – Mack (presentation)	420

Air

46	National Picture of Ambient Air Toxics – Hafner and McCarthy (abstract)	438
47	What is the National Picture of Air Toxics Concentrations? – Hafner and McCarthy (presentation)	439
48	Collection and Analysis of Acrolein Using Compendium Method TO-15 – Swift, et al (paper)	451
49	Collection and Analysis of Acrolein Using Compendium Method TO-15 – Swift, et al (presentation)	464
50	Using Selected Halocarbons as Sample Monitoring Compounds for the Analysis of TO-15 Air Toxics – Whipple and Harmon (presentation)	478
51	Collection and Analysis of Hexavalent Chromium in Ambient Air – Swift, et al (paper)	493
52	Collection and Analysis of Hexavalent Chromium in Ambient Air – Swift, et al (presentation)	506
53	Passive Monitoring of Ground Level Ozone – Mathew (abstract)	518
54	Passive Monitoring of Ground Level O_3 , NO_2 , SO_2 , and NH_3 in Ambient Air with Subsequent Analysis by Ion Chromatography – Mathew (presentation)	519

Wednesday A.M., August 30, 2006

page

Organic Methods

55	Enhancements of EPA Method 535 – Krol (abstract)	541
56	Enhancements of EPA Method 535 – O'Connor (presentation)	542
57	Stir Bar Sorptive Extraction (SBSE) Sample Preparation for Aqueous Environmental Samples: An Overview – Pfannkoch, et al (abstract)	551
58	Stir Bar Sorptive Extraction Environmental Applications – Pfannkoch, et al (presentation)	552
59	Methamphetamine and Beyond – DiRienzo, et al (abstract)	579
60	Methamphetamine and Beyond – DiRienzo, et al (presentation)	580
61	Two Novel Reversed Phase HPLC Columns for the Baseline Resolution of Explosives Compound of Environmental Interest – Later, et al (presentation)	608

Chemical Speciation – Hg, Se, and Br Species

62	Speciation of Mercury in Human Hair – Fahrenholz, et al (abstract)	622
63	Evaluation of Literature Methods Used in Speciation of Mercury in Human Hair: Application of Speciated Isotope Dilution Mass Spectrometry (SIDMS, EPA Method 6800) as a Diagnostic Tool for Accurate Analysis – Mizanur Rahman, et al (presentation)	623
64	Liquid Chromatographic Mercury Speciation: A Suite of New Techniques Employing Solid-Phase Extractions and Liquid-Phase Transfers and Separations – Shade (abstract)	644
65	Liquid Chromatographic Mercury Speciation: A Suite of New Techniques Employing Solid-Phase Extractions and Liquid-Phase Transfers and Separations – Shade (presentation)	645
66	Analytical Methods for Selenium Speciation: The Good, The Bad, and The Ugly – Gerads and Gürleyük (abstract)	665
67	Analytical and Preparatory Issues Associated with Total Selenium and Selenium Speciation Analysis – Gerads and Gürleyük (abstract)	666
68	Improved Bromate/Bromide Speciation Drinking Water by HPLC/ICP-MS – Perrone, et al (paper)	667
69	Improved Bromate/Bromide Speciation in Drinking Water by HPLC/ICP-MS – Perrone, et al (presentation)	677

Inorganic Methods

70	Implementation of the Methods Innovation Rule as a Major Factor in the RCRA Performance- Based Measurement (PBMS) Program – Lesnik (abstract)	695
71	Implementation of the Methods Innovation Rule (MIR) as a Major Factor in the RCRA Performance-Based Measurement (PBMS) Program – Lesnik (presentation)	696
72	Current Status: RCRA Inorganic Methods Development Program – Yang (presentation)	713
73	Sample Preparation of Electronic Components to Ensure Compliance with the New RoHS/WEEE Regulations – Bath and Batzke (abstract)	726
74	Sample Preparation of Electronic Components to Ensure Compliance with the New RoHS/WEEE Regulations – Bath (presentation)	727
75	Inorganic Analysis for Environmental RoHS Compliance – Grosser and Thompson (paper)	749
76	Inorganic Analysis for Environmental RoHS Compliance – Grosser and Thompson (presentation)	758
77	Modern Interference Correction Including Cell-Based Technology for ICP-MS Environmental Analyses – Foglio and Neubauer (abstract)	773
78	Modern Interference Correction Including Cell-Based Technology for ICP-MS Environmental Analyses – Foglio and Neubauer (presentation)	774
79	Determination of Total Cyanide without Distillation – Lipps (paper)	799
80	Total Cyanide without Distillation – Lipps (presentation)	808

Homeland Security

81	Building Environmental Laboratory Capability in Support of Emergency Response – Antley (presentation)	831
82	Environmental Laboratory Response Network – Rothman (abstract)	843
83	EPA's National Homeland Security Research Center: Response Capability Enhancement – Rothman (presentation)	844
84	Sampling and Analytical Planning for Re-Entry and Recovery Following a Chemical Release Incident: Thinking Ahead – Hewett and Kimmell (abstract)	856
85	Sampling and Analytical Planning for Re-Entry Following a Chemical Release Incident: Thinking Ahead – Kimmell and Hewett (presentation)	857
86	ETV and Real World Deployment Testing of an On-line, Learning-based system for Drinking Water Security Monitoring – Kroll, et al (paper)	870
87	Operational and Laboratory Verification Testing of a Heuristic Online Water Monitoring System for Security – Kroll, et al (presentation)	890
88	Hand-Portable Toroidal Ion Trap Detector for Homeland Security – Contreras, et al (abstract)	919
89	Hand-Portable GC-MS for CBA Detection – Later, et al (presentation)	920
90	Laboratory Capability in Support of Emergency Response – Fitz-James (abstract)	943

Wednesday P.M., August 30, 2006

Organic Methods

91	Recent Advances in Thermal Desorption – Grosser and Tipler (abstract)	945
92	Recent Technical Advances in Thermal Desorption – Gas Chromatographic Instrumentation for Fully Automated Ozone Precursor Analysis – Grosser and Tipler (paper)	947
93	EPA Quantification of Low Molecular Weight Alcohols, Ketones, and Ethers Using Headspace Trap GCMS – Goodman and Grecsek (paper)	955
94	EPA Quantification of Low Molecular Weight Alcohols and Ethers Using Headspace Trap GCMS – Goodman and Grecsek (presentation)	961
95	Variables in Lipids Analyses and Affect on Data Quality – Hutchings and Bailey (paper)	979
96	Variables in Lipids Analyses and Affect on Data Quality – Hutchings and Bailey (presentation)	987
97	Quantitative Defense of Extract Dilution for Hydrocarbon Interferences in Semi-Volatile Organic Analysis by GC/MS – Bruce, et al (paper)	996
98	Quantitative Defense of Extract Dilution for Hydrocarbon Interferences in Semi-Volatile Organic Analysis by GC/MS – Bruce, et al (presentation)	1006
Chemical Speciation – Cr (VI) Species		

page

99	A New Tool to Assure the Accuracy of Cr (VI) Measurements – Buckley, et al (abstract)	1020
100	A New Tool to Assure the Accuracy of Cr (VI) Measurements – Nagourney (presentation)	1021
101	Recovery of Chromium Species from Soils: What Factors Are Most Important? – Buckley, et al (abstract)	1034
102	Recovery of Chromium Species from Soils: What Factors Are Most Important? – Buckley, et al (presentation)	1035
103	Species Analysis During Measurements Process – Bath, et al (paper)	1053
104	Achieving Quantitative Species Analysis When Analytes Turn into Other Analytes During the Measurement Process – Kingston, et al (presentation)	1057
105	Using Method 6800 for Chromium (VI) Analysis – Bruce, et al (abstract)	1076

106	The Commercialization of Method 6800 – Speciated Isotope Dilution Mass Spectrometry for the Determination of Hexavalent Chromium – Vicinie, et al (paper)	1077
107	The Commercialization of Hexavalent Chromium Determination Using Method 6800 with Speciated Isotope Dilution Mass Spectrometry (SIDMS) – Vicinie, et al (presentation)	1082

Accreditation

108	The History of NELAC – Autry (presentation)	1090
109	The Future of NELAC: Progress Update – Shields (presentation)	1097
110	The Changing Role of INELA in Standards Development – Parr (presentation)	1109
111	NELAC Self-Sufficiency – Epstein (presentation)	1124

Perchlorate

112	Analysis of Perchlorate in Drinking Water – Munch and Pepich (abstract)	1162
113	A Review of the USEPA Methods for the Analysis of Perchlorate in Drinking Water – Pepich and Munch (presentation)	1163
114	New EPA Office of Solid Waste SW-846 Methods for the Analysis of Perchlorate in Various Environmental Matrices – Yang and Drop (paper)	1181
115	DoD Perchlorate Handbook – Ingersoll and McLean (abstract)	1188
116	Sound Strategies for Collecting Environmental Data on Emerging Contaminants DOD Perchlorate Handbook – Ingersoll and McLean (presentation)	1189
117	Determination of Perchlorate Using High Performance Liquid Chromatography/Mass Spectrometry (LC/MS) – DiRienzo (presentation)	1202

page

Thursday, August 31, 2006

Superfund Analytical Services

118 How to Win a CLP Contract – Stewart (presentation) 1220 119 Modernization of the Superfund Contract Laboratory Program (CLP) - Nebelsick and Cocuzza 1225 (presentation) 120 Automated Review of Staged Electronic Data Deliverable (SEDD) Stage 3 Deliverables -1239 Mudambi (presentation) 121 Performing Automated Data Review and Data Quality Assessment on SEDD Files - Denzer 1251 (abstract) 122 Commercial Laboratory Perspectives on CLP Program – DiRienzo 1252 **Information Management** 123 Staged Electronic Data Deliverable (SEDD) – Overview and Implementation Status –Mudambi 1257 (paper) Staged Electronic Data Deliverable (SEDD) - Overview and Implementation Status - Mudambi 1262 124 (presentation) A Technical Overview of the Staged Electronic Data Deliverable (SEDD) - Solsky (paper) 1272 125 A Technical Overview of the Staged Electronic Data Deliverable (SEDD) – Solsky (presentation) 126 1276 127 AnIML for Interchanging Analytical Data - Kramer (abstract) 1285 128 Analytical Information Markup Language (AnIML): A New Mechanism for Interchanging and 1286 Archiving Analytical Chemistry Data – Kramer (presentation) 1305 129 Long Term Storage of Chromatographic Data – O'Neill (paper) Long Term Storage of Chromatographic Data... AnIML, TNF, Viewers, and Plenty of Challenges! 130 1311 - O'Neill (presentation)

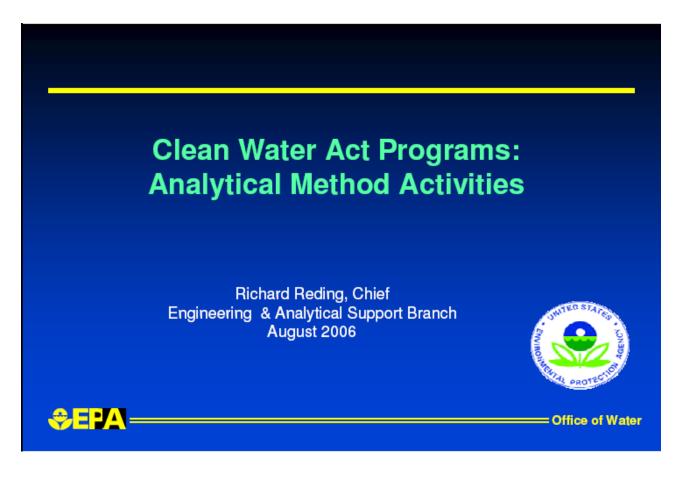

131	Developing an Intranet-Based Quality Management System to Incorporate Measurement and Reporting – Haddad and Worthington (abstract)	1321
132	OEI Quality System: An Introduction – Haddad and Worthington (presentation)	1322
The Pe	erformance Approach	
133	How a Concensus Measurement Model will Improve Overall Environmental Monitoring – Worthington and Haddad (presentation)	1332
134	Improving the Health of Environmental Monitoring When Using EPA Test Methods – Houck, et al (abstract)	1366
135	Improving the Health of Environmental Monitoring When Using EPA Test Methods – Schrenkel, et al (presentation)	1367
136	The Good, The Bad, and The Ugly Revisited: Environmental Testing in the 21 st Century – Burrows (abstract)	1377
137	The Good, The Bad, and The Ugly Revisited – Burrows (presentation)	1378
138	Performance-Based Measurement Systems – Blye and Vitale (abstract)	1396
139	Performance-Based Measurement Systems: A Double-Edged Sword - Buyer Beware – Blye and Vitale (presentation)	1397
140	Development of New EPA Promulgated Methods – Later and Munch (abstract)	1406
141	A Collaborative Approach to the Timely Development of New EPA Promulgated Methods for Emerging Environmental Contaminants – Later and Munch (presentation)	1407

Perchlorate

142	Two-Dimensional Ion Chromatographic Method – Later, et al (abstract)	1418
143	A Two-Dimensional Ion Chromatographic Method for the Ultra-Low Level Determination of Perchlorate and Bromate Using Suppressed Conductivity Detection –Later, et al (presentation)	1419
144	Trace Level Determination of Perchlorate in Soils and Saltwater by Tandem Suppressed Conductivity and Mass Spectroscopy (IC/MS) – Gandhi (abstract)	1433
145	Trace Level Determination of Perchlorate in Soils and Saltwater by Tandem Suppressed Conductivity and Mass Spectroscopy (IC/MS) – Gandhi (presentation)	1434
146	The Highest Levels of Perchlorate Detected in Foods and Beverages by Ion Chromatography Coupled with Tandem Mass Spectrometry (IC-ESI-MS/MS) – Antonsen, et al (abstract)	1453
147	The Highest Levels of Perchlorate Detected in Foods and Beverages by IC-ESI-MS/MS: World-Wide Survey – El Aribi, et al (presentation)	1454
148	Rapid Determination of Perchlorate Anion in Foods and Environmental Samples by Ion Chromatography-Tandem Mass Spectrometry – Hopper, et al (abstract)	1472
149	Rapid Determination of Perchlorate Anion in Foods and Environmental Samples by Ion Chromatography-Tandem Mass Spectrometry – Krynitsky, et al (presentation)	1473

NEMC 2006 PROCEEDINGS

MONDAY, AUGUST 28, 2006 SPECIAL SESSION ON DETECTION AND QUANTITATION LIMITS

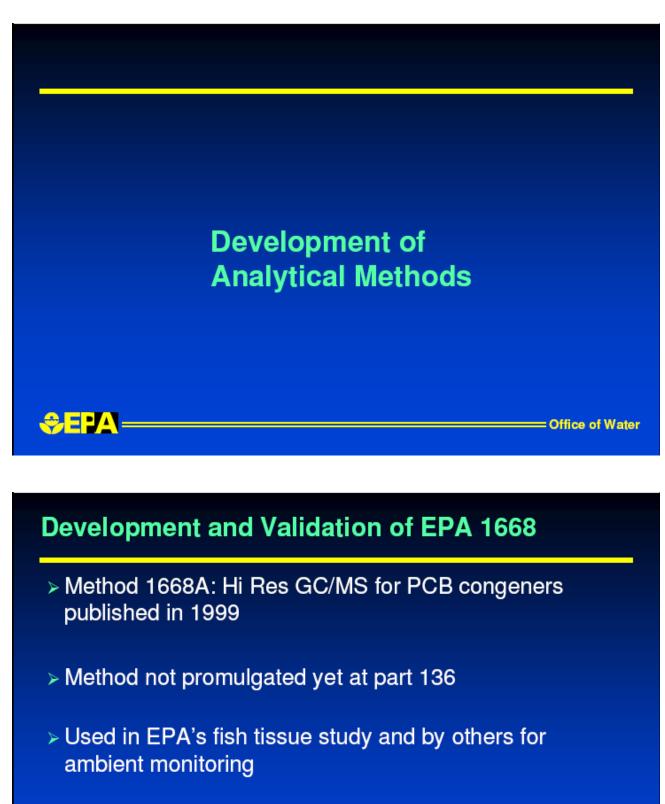

Analytical Methods Activities

- Development of Analytical Methods
- >Rulemakings
- Federal Advisory Committee on Detection and Quantitation

------- Office of Water

> Additional validation study in wastewater completed

Development and Validation of EPA 1614

- Method 1614: GC/Hi Res MS for PBDEs brominated flame retardants – published August 2003
- > Method not promulgated yet at part 136
- > Developed at Axys Analytical
 - 8 PBDEs of primary concern measured by isotope dilution
 - 36 other PBDE congeners measured by internal standard
- Multiple single-laboratory validation of Method 1614 completed in 2005

EPA/ASTM Method for NP and APEs

Nonylphenol (NP) and alkylphenol ethoxylates (APEs) are surfactants

> Collaborating with ASTM to develop & validate method

- Status
 - Draft ASTM method written by Schenectady International, Inc.
 - Holding time study by EPA Region 5 showed sample holding time can be 28 days when samples are preserved with acid
 - Interlab validation study started June 2006
 - -All laboratories are volunteers
 - -Region 5 lab is EPA lead

Office of Water

Microbiological Method Development and Validation

- Method 1600: Enterococci in wastewater and Combined Sewer Overflows (CSOs)
- Method 1603: E. coli in wastewater and CSOs
- > Both methods:
 - Validated in wastewater at 12 laboratories
 - Wastewater report completed May 2005
 - Validation in CSOs ongoing (weather dependent)

Office of Water

Microbiological Method Development and Validation (cont.)

- Method 1103.1: E. coli in wastewater and CSOs
 - Validated in wastewater at 10 laboratories
 - Wastewater report completed June 2005
 - Validation in CSOs ongoing (weather dependent)
- Method 1106.1: Enterococci in wastewater and CSOs
 - Validated in wastewater at 10 laboratories
 - Validation study report completed in May 2005
 - Validation in CSOs ongoing (weather dependent)

------- Office of Water

Microbiological Method Development and Validation (cont.)

Method 1680 and 1681: Fecal coliforms in biosolids

- Study completed December 2002
- Evaluated in 5 biosolids matrices at 12 participant laboratories
- Validation study report completed in January 2005
- > Method 1682: Salmonella in biosolids
 - Study completed May 2003
 - Evaluated in 4 biosolids matrices at 12 participant laboratories
 - Validation study report completed in January 2005

Contraction of Water

Microbiological Method Development and Validation (cont.)

- Method 1693: Cryptosporidium and Giardia in wastewater and CSOs
 - Single-laboratory study completed December 2005
 - Interlaboratory validation in CSOs and wastewaters
- Method 1606 and 1607: Enterococci in fresh water, wastewater, and marine waters
 - Both methods use quantitative polymerase chain reaction (PCR)
 - Interlaboratory validation underway

= Office of Water

Microbiological Method Holding Time Studies

Methods 1600, 1603, 1103.1, 1106.1 (enteroc., e. coli,)
 Ambient waters (recreational, beaches, fresh, and marine)

 13 laboratories total
 Analyses complete
 Report expected soon

 Methods 1680, 1681, and 1682 (fecal & salmonella)
 Biosolids

 29 participant laboratories
 Expected completion date September 2006
 Report expected in 2006

Other Ongoing or Potential Projects

- Revised "Pumpkin Book" expected Fall '06
 - Suggests how to demonstrate then fix matrix problems

> Depending on program priorities and resources

- Hi Res GC/MS for pesticides
- Hormones, steroids, prescription and OTC drugs PPCPs
- Helminth ova (parasite) in biosolids
- Enteric (human) viruses in biosolids

ANALYTICAL METHODS CONTACTS

> Our methods website

www.epa.gov/waterscience/methods

Chemistry Methods

- Lemuel Walker: Walker.Lemuel@EPA.gov
 - -ATPs, oil & grease, pumpkin book, metals, cyanide
- Brian Englert: <u>Englert.Brian@EPA.gov</u>
 PPCPs, PBDEs, NPs, APEs

Microbiology Methods and ATPs

Robin Oshiro: Oshiro.Robin@EPA.gov

-------Office of Water

<section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><section-header><image>

August 2005 Microbiology Proposed Rule

- Proposed EPA Methods 1600, 1603, 1103.1, 1106.1, 1680, 1681, and 1682 at 40 CFR part 136
 - Includes enterococci, e. coli, fecal coliforms, salmonella
 - August 16, 2005 (70 FR 48255)
 - Comment period closed
 - Final rule expected in fall of 2006

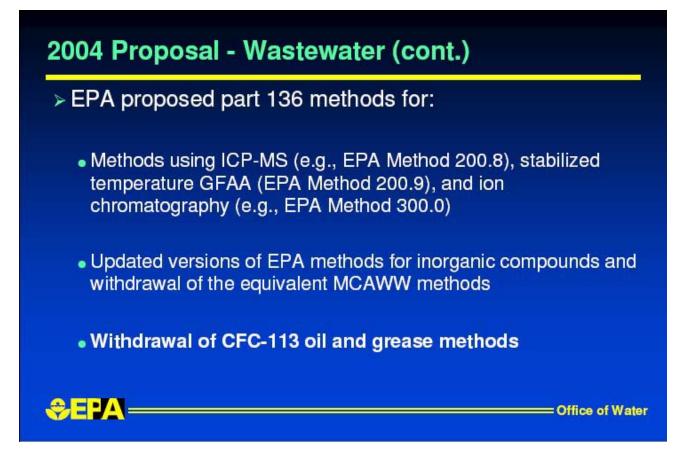

April 2004 CWA/SDWA Methods Proposed Rule

- EPA proposed revisions and updates to wastewater and drinking water methods and monitoring regulations on April 6, 2004 (69 FR 18166).
 - Drinking water methods
 - Wastewater methods
 - Other updates to wastewater regulations
- > Final rule signed in 2006; publish Sept '06?
 - Pretty much approves everything proposed in 2004

€PA =

Office of Water

2004 Proposal – Wastewater (cont.)

- Updates to clarify requirements for grab and composite sampling (at 40 CFR parts 122, 136, and 403)
- New sample handling, collection and preservation requirements, e.g. cyanide interferences
- Increased options for method flexibility, including new requirements that clarify procedures for validation of minor modifications to approved methods and the use of capillary columns with GC methods – 40 CFR 136.6

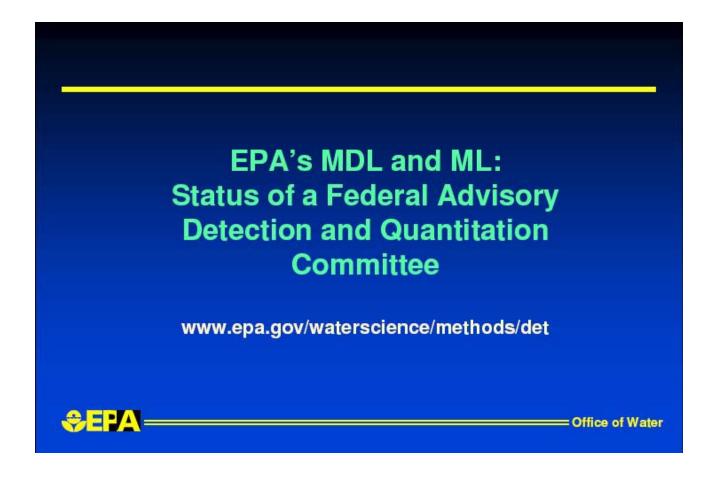

RULEMAKING CONTACTS

- > Our methods website
 - www.epa.gov/waterscience/methods

Rule Managers

- Meghan Hessenauer: Hessenauer.Meghan@EPA.gov
- Marion Kelly:Kelly.Marion@EPA.gov
- Pat Fair (drinking water): Fair.Pat@EPA.gov
- Robin Oshiro: Oshiro.Robin@EPA.gov

Why are we looking at detection & quantitation?

- Longstanding concerns about how an MDL or ML is calculated and used in lab & regulatory programs
- EPA proposed changes to the MDL and ML in 2003
- > 136 comments some supportive, most not. Theme:
 - We could do better
 - Let's try a collaborative process
- > We decided to:
 - Withdraw proposed changes
 - Commission a "situation assessment" by a neutral facilitator

Common Issues From the Situation Assessment

- Variability and reliability of results within and between laboratories and over time
- Need to address background contamination, matrix and recovery effects, false positive and negative rates
- What results should be reported MDL? ML?
- Need for common set of terms and definitions
- Inconsistent uses of detection and quantitation limits by Federal, State and local regulators; inconsistencies among EPA programs - CWA, RCRA, SDWA

Office of Water

Detection/Quantitation Committee Formation

- May 2005 established a FACA committee to recommend ways to improve the calculation and use of MDLs and MLs
 - 21 members
 - Scope is CWA programs
 - Committee considering several alternatives to the "Appendix B" MDL
- Name Federal Advisory Committee on Detection and Quantitation Approaches and Uses in Clean Water Act Programs (the FACDQ or Committee)
- > FACDQ website www.epa.gov/waterscience/methods/det

Purpose of this Advisory Committee

Provide group advice and consensus recommendations on approaches for development of detection and quantitation procedures, and uses of these procedures in EPA's <u>Clean Water Act Programs</u>.

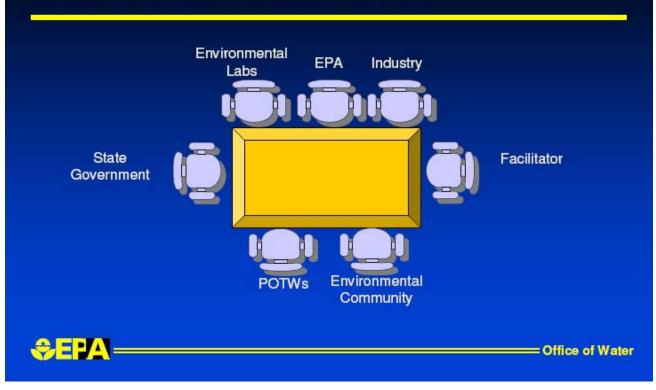

= Office of Water

FACDQ Desired Product

- Reach agreement on
 - Definition of terms
 - One or more specific approaches for detection and quantitation for CWA
 - Interpretation and uses of the numbers
- > Revised detection and quantitation approaches
 - acceptable to most or all
 - easy to carry out
 - practical and
 - cost-effective
- > Produce accurate, consistent and uniform results
- > Used to inform a rulemaking

FACDQ Committee Composition

FACDQ Membership

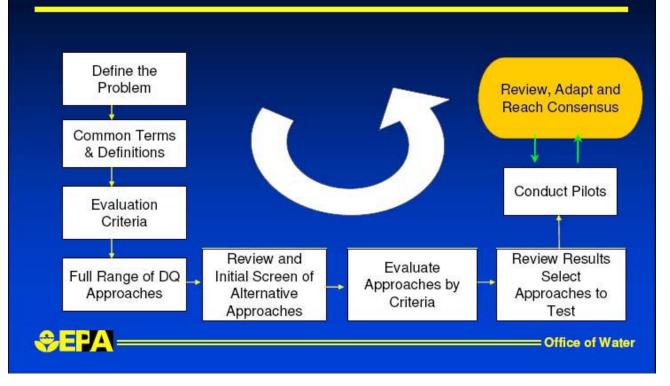

- Environmental Community 4 members
 - NWF, Environmental Advocates of NY, TN Public Employees for Env. Responsibility, University Professor
- Environmental Laboratory Community 4 members
 - Large, Medium, Small Laboratories; Instrument Manufacturer
- > Regulated Community 4 members
 - Ford Motor Co., Pulp and Paper Industry, API, Exelon
- Water Utility Community 4 members
 - NACWA, Hampton Roads VA, Louisville KY, ACWA (CA)
- State Government 4 members
 - . CO, MI, WI, FL
- EPA-1 member

EPA

Office of Water, Office of Science & Technology (CWA)

-------Office of Water

FACDQ Committee Process

FACDQ Committee Meetings and Workgroups

FACDQ Meetings – Open to Public

- June 21-22, 2005
- September 29-30 2005
- December 8-9, 2005
- March 29-30 2006
- July 13-14, 2006
- Pending December 6-8, 2006
- > Established Two Workgroups
 - Policy Workgroup
 - Technical Workgroup
- > Working documents and meeting notes on website

€PA =

Office of Water

FACDQ Committee Policy Workgroup (cont'd)

> Actions of Policy Workgroup

- Developed descriptions of uses
 - Extensive outreach, polling within each caucus
- Developed preliminary data quality objectives (DQOs) and measurement quality objectives (MQOs) for:
 - Detection and quantitation procedures
 - Pilot studies for establishing detection and quantitation limits

Calculation Procedures Under Consideration

Detection limit procedures

- American Council of Independent Laboratories (ACIL)
- Consensus Group
- Hubaux-Vos
- ASTM D6091 Interlaboratory Detection Estimate (IDE)
- EPA "Appendix B" Method Detection Limit (MDL)
- Quantitation limit procedures
 - ASTM D6512 Interlaboratory Quantitation Estimate (IQE)
 - EPA Lowest Concentration Minimum Reporting Level
 - EPA Minimum Level of Quantitation (ML)
 - ACIL
 - Consensus Group

\$EPA=

------ Office of Water

Pilot Status

- Piloting three candidate procedures developed by labs (ACIL), ASTM (IDE/IQE), EPA (not the MDL/ML)
 - 5 analytical methods to be evaluated with each candidate procedure
 - Metals by EPA Method 200.7 (ICP-OES)
 - Inorganic ions by EPA Method 300.0 (ion chromatography)
 - Total cyanide by spectrophotometry (EPA Method 335.x)
 - Organochlorine pesticides by GC/ECD (EPA Method 608)
 - Semi-volatile organics by GC/MS (EPA Method 625
 - Schedule
 - Pilot design approved July 2006
 - Labs analyze samples September October 2006
 - Draft report late 2006
 - Report to FACDQ February 2007

FACDQ Information

- > Detection/Quantitation website: www.epa.gov/waterscience/methods/det
- Designated Federal Officer (DFO) Dick Reding

ESTIMATING DETECTION QUANTITATION LIMITS

Burrows, Richard; Severn Trent Laboratories

A Procedure for estimating detection and quantitation limits has been drafted by ACIL (American Council of Independent Laboratories). This paper will describe the details of the procedure and the reasons for each of the steps

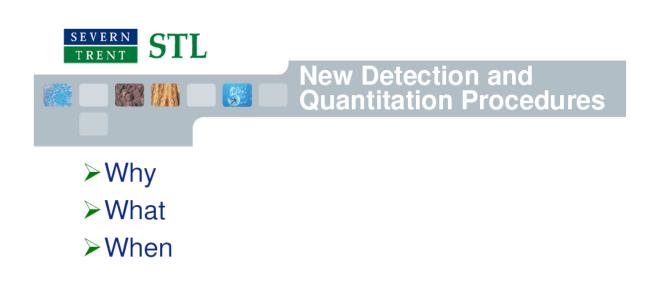

- Censored vs. Uncensored methods
- Precision and Bias
- False positives and False negatives
- Data reporting recommendations

The ACIL Detection and Quantitation Limit Procedure

Richard Burrows

NEMC 2006

Why a New Detection Limit Procedure?

 There is no requirement for or measure of precision at the ML
 There is no measurement of or requirement for accuracy at the ML

Procedure

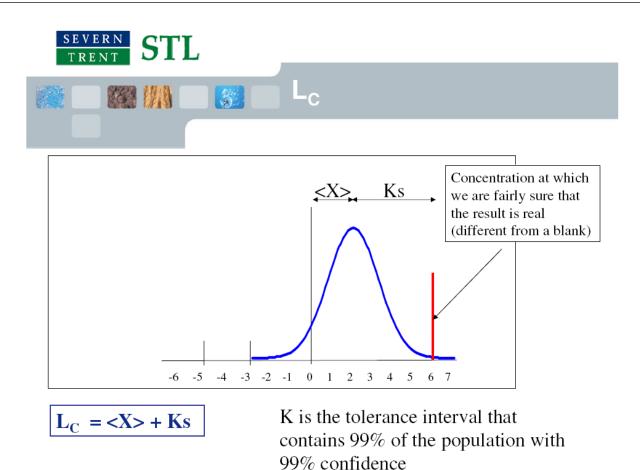

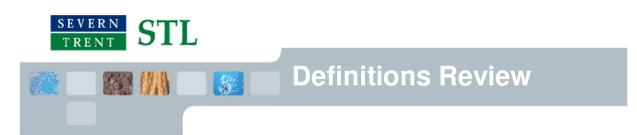

"Uncensored methods"

 Avoids any issues with dependence of variability on concentration

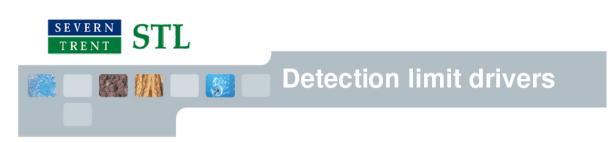

The critical value (L_C) is the lowest result that can be distinguished from a blank. The MDL is a type of critical value.

The detection limit (L_D) is the lowest true concentration that can be reliably detected.

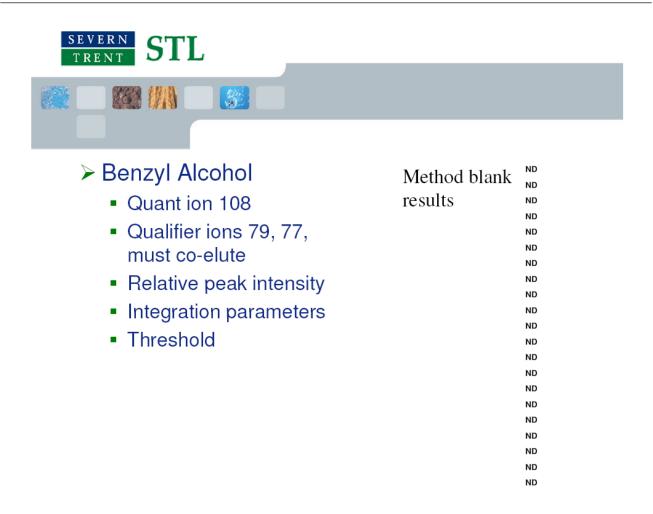

2. Ability to Qualitatively identify analytes

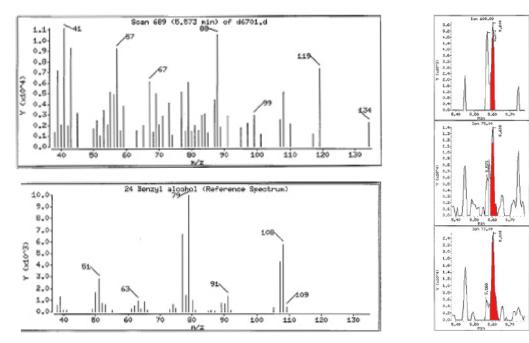

Typical environmental examples are GC and GC/MS

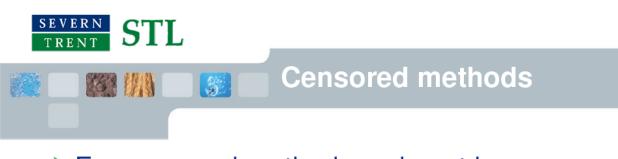

- Is the peak above the threshold?
- Is the peak integrated?
- Are the qualifier ions present and integrated?
- Are the ion ratios correct?

Characterized by blanks that are usually ND

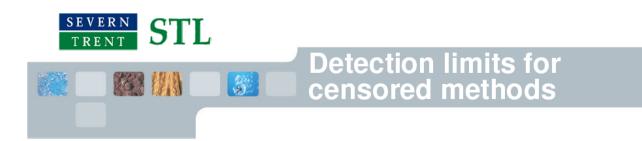

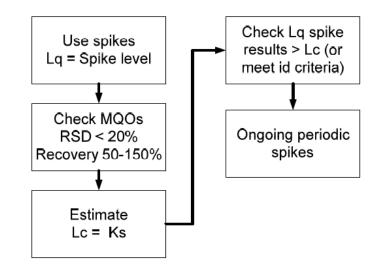

For censored method we do not have any numerical blank results

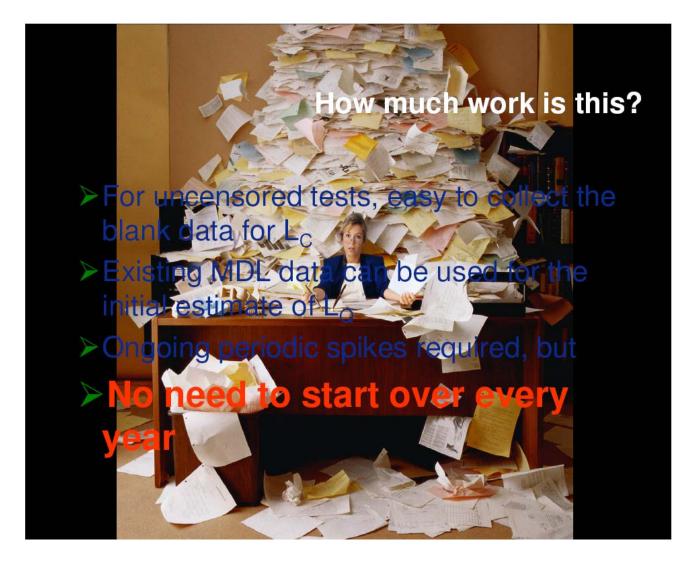

So, must start with spikes

 Once per year recalculate Lc based on recent blanks and update if necessary
 Run Lq verifications once per quarter

Questions?

A Simple Procedure for Determination of Method Quantitation Limits

Chung-Rei Mao

U.S. Army Corps of Engineers; HTRW Center of Expertise, Omaha, Nebraska

ABSTRACT

Method Quantitation Limit (MQL) is the lowest amount of analyte in a sample that can be quantitatively determined with stated, acceptable precision and accuracy (bias) under stated analytical conditions.

MQL is commonly determined or estimated based on professional judgments, multiples of the Method Detection Limit (MDL), or empirical methods of replicate analyses of fortified samples at low concentrations. Information on precision and accuracy are usually not available for an estimated MQL so that the estimated MQL would be of limited or no practical value. Empirical methods may produce MQL of known precision and bias; however, consistent and cost effective procedures are not established yet.

This paper presents a simple procedure for determination of MQL based on laboratory's MDL and the Laboratory Control Sample (LCS) data, which are readily available in most environmental laboratories. An MQL determined based on the LCS and MDL data has well defined precision and bias and does not need additional analysis. Environmental data at or above the determined MQL will have reliable precision and bias for decision-making.

INTRODUCTION

Method Quantitation Limit (MQL) is an important analytical parameter that does not have a consistent and universal definition, determination procedure, and usage in the environmental testing industries. There are many different names for MQL, such as Limit of Quantitation (LOQ), Minimum Level (ML), Practical Quantitation Limit (PQL), Estimated Quantitation Limit (EQL), Contract-Required Quantitation Limit (CRQL), etc., each with somewhat different definitions, determination procedures, and applications (USEPA October 2004).

The MQL is defined here as "the lowest amount of analytes in a sample that can be quantitatively determined with stated, acceptable precision and accuracy (bias) under stated analytical conditions". This definition is based on the International Conference on Harmonization (ICH) Harmonised Tripartite Guideline (ICH 1994). According to this definition, the data precision and bias of MQLs must be known and reported.

MQL is generally determined or estimated based on the following categories of common procedures: (1) professional judgment, (2) multiples of detection limit, (3) lowest calibration standard, and (4) empirical procedures. The "professional judgment" procedure is based on historical quantitation limits, USEPA Performance Evaluation Study data, or arbitrary data uncertainty (e.g., RSD < 10%). The "multiples of detection limit" procedure determines MQLs usually based on an arbitrary multiple of 3 - 10 times the detection limits. The "lowest calibration standard" procedure establishes the MQL at the lowest calibration standard. For most

analytical methods, however, calibration standards do not take into account of sample preparation uncertainty, and the acceptance of the lowest calibration standard depends significantly on the calibration techniques (e.g., number, distribution, weighing factor of the calibration standards). The "empirical procedures" is probably the best method for determining reliable MQLs and is based on replicate analyses of a series of spiked samples of various concentrations around the MQL. However, standard procedures and consistent criteria for empirical procedures have not been established, and reliable empirical procedures are generally very expensive.

USEPA recently proposed an empirical procedure for determining the "Lowest Concentration Minimum Reporting Level (LCMRL)" for the Unregulated Contaminant Monitoring Regulation (UCMR). This USEPA-proposed procedure determines the LCMRL or quantitation limit based on percent recoveries and prediction intervals of a series of replicate samples (USEPA November 2004). The LCMRL procedure is complicated and expensive for implementation, and it may not be reliable due to issues on the use of parametric statistics, prediction intervals, etc. This paper presents a simple empirical procedure for determination of MQLs based on laboratory's in-house QC data of Method Detection Limit (MDL) study and LCS control limits (CLLCS).

Concepts and Procedures

The proposed procedure for MQL determination is based on the data precision of an analytical system. Data precision at various concentrations is estimated based on the routine laboratory QC data of MDL study and LCS control limits. Data bias is not considered because of larger relative error in quantifying censored data at lower concentrations than the lowest calibration standard. Figure 1 shows data uncertainty versus analyte concentrations of a typical analytical system.

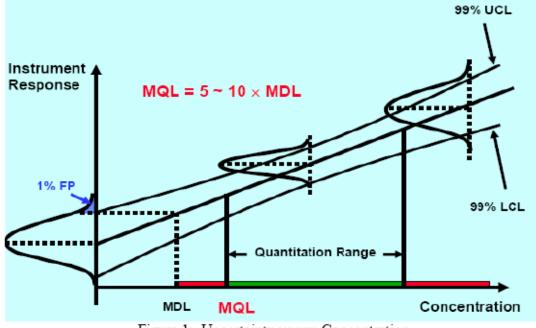

Figure 1: Uncertainty versus Concentration

Data uncertainty is approximately constant within the quantitation range and increases at concentrations outside the quantitation range. The lower limit of the quantitation range is the MQL, which may be 5 - 10 times greater than the MDL. The data precision and bias at the MQL is reported based on the relative standard deviation (RSD) and mean percent recovery (%R) of the LCS, respectively.

Based on physical characteristics of constant measurement uncertainty at low concentrations and proportionally increasing uncertainty at higher concentrations, Rocke and Lorenzato proposed a two-component model for measurement uncertainty (Rocke and Lorenzato 1995)

$$c = \varepsilon + \mu e^{\eta} \tag{1}$$

where c is measured concentration, μ is true concentration, and ε and η are normally distributed uncertainty with mean 0 and standard deviations σ_{ε} and σ_{η} , respectively. The uncertainty of a measurement at concentration c, σ_c , would be:

$$\sigma_c = \sqrt{\sigma_c^2 + \mu^2 e^{\sigma_{\eta}^2} \left(e^{\sigma_{\eta}^2} - 1 \right)}$$
⁽²⁾

Equation 2 illustrates the key feature of the two-component model, i.e., the nearly constant component, σ_{e}^{2} , at low concentrations and the proportional component, $\mu^{2}e^{\sigma_{\pi}^{2}}(e^{\sigma_{\pi}^{2}}-1)$, at high concentrations. Figure 2 shows the constant component (dashed line), proportional component (dotted line), and the total standard deviation (solid line) versus concentration.

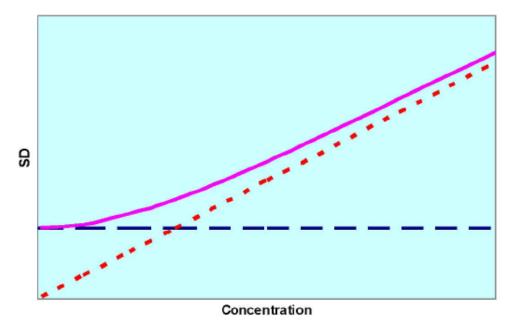

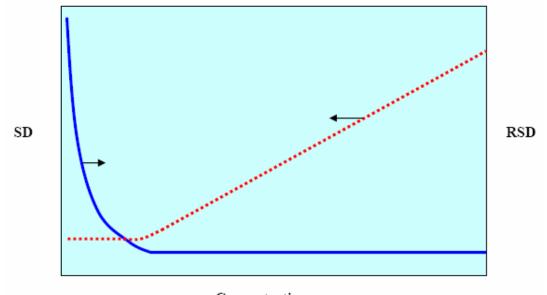

Figure 2: Uncertainty versus Concentration Based on Rocke-Lorenzato Two-component Model

For a linear calibration curve, Rocke-Lorenzato model approximates a constant SD at low concentrations and a constant RSD at high concentrations (Figure 3).

Concentration Figure 3: SD and RSD versus Concentration

Figure 3 shows that the RSD decreases quickly as the concentration increases and reaches a constant value, which is equal to the RSD at higher concentrations. The RSD at lower concentrations may be estimated based on the MDL study (or method blank data) and the RSD at higher concentrations may be estimated based on the LCS control limits. The minimum concentration where the RSD based on the MDL study equals to the RSD based on the LCS control limits determines the MQL. Analytical data should have constant RSD at and above the MQL within a quantitation range.

The relative uncertainty, $U_{95\%}$, at low concentration c is defined as:

$$U_{95\%} = \pm \frac{t_{(n-1, 975)} \times \sigma_c}{c} \times 100\%$$
(3)

where $t_{(n-1,.975)}$ is the two-tailed Student's *t* value for an estimated SD, σ_c , with *n*-1 degrees of freedom at a 95% confidence level, and σ_c is the estimated SD of replicate analyses at a low concentration *c* and may be expressed with the Rocke-Lorenzato two-component model.

$$U_{95\%} = \pm \frac{t_{(n-1,.975)} \times \sqrt{\sigma_{e}^{2} + \mu^{2} e^{\sigma_{\pi}^{2}} (e^{\sigma_{\pi}^{2}} - 1)}}{c} \times 100\%$$
(4)

The proportional component of the Rocke-Lorenzato model may be expanded and approximated with the first order of Taylor series if σ_{η} is small and approximately equal to σ_{ε} at low concentration *c*.

$$U_{95\%} \approx \pm \frac{t_{(n-1,.975)} \times \left(\sqrt{2} \times \sigma_{\varepsilon}\right)}{c} \times 100\%$$
(5)

Let $c = N \times MDL$ and $MDL = t_{(n-1,.99)} \times \sigma_{\varepsilon}$,

$$U_{95\%} = \pm \frac{t_{(n-1,.975)} \times \left(\sqrt{2} \times \sigma_{\varepsilon}\right)}{t_{(n-1,.99)} \times \sigma_{\varepsilon}} \times \frac{100\%}{N}$$

$$\tag{6}$$

where $t_{(n-1,.99)}$ is the one-tailed Student's *t* value for an estimated SD, σ_{ε} , with *n*-1 degrees of freedom at a 99% confidence level, and σ_{ε} is the estimated SD of replicate analyses of an MDL study. For concentrations near an MDL study,

$$U_{95\%} \approx \pm \frac{100\%}{N}$$
(7)

Equation (7) shows that the relative uncertainty, $U_{95\%}$, at low concentration c may be approximated as $\pm 100\%$ divided by N, a multiple of the MDL. For example, $U_{95\%} \approx \pm 100\%$, 50%, 33%, 20%, and 10% at N = 1, 2, 3, 5, and 10, respectively. The relative uncertainty cannot continuously decrease at higher N or concentrations, i.e., $U_{95\%} \neq 1\%$ at N = 100, but would be superseded by the warning limits of the LCS (WLLCS).

Figure 4 shows that the relative uncertainty drops as the concentration increases and the MQL is set at the concentration where the $U_{95\%} = WL_{LCS}$.

$$\frac{100\%}{N} = \frac{t_{(n-1,.975)} \times \sigma_{LCS}}{C_{LCS}}$$
(8)

$$\approx 2 \times RSD_{LCS}\%$$
 (9)

where $t_{(n-1, ..., 075)}$ is the two-tailed Student's *t* value for an estimated SD, σ_{LCS} , with *n*-1 degrees of freedom at a 95% confidence level, and σ_{LCS} and *RSDLCS* are the estimated SD and RSD of replicate LCS analyses at mean recovered concentration, *CLCS*, respectively.

$$N = \frac{100}{WL_{LCS}} = \frac{100}{2 \times RSD_{LCS}}$$
(10)

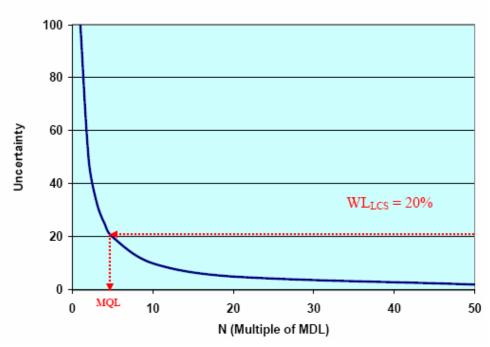

Figure 4: Relative Uncertainty, U95%, versus N

An MQL is therefore a multiple of the MDL, i.e., $MQL = N \times MDL$, where the multiple, N, is determined based on laboratory's in-house performance data of MDL study and LCS control limits. The data precision and bias at concentrations at and above the MQL are the same as the RSD and mean %R of the LCS. An example determination of MQL using the proposed MQL procedure is shown below:

For a laboratory with MDL = 1 ppb and LCS control limits = 60 - 120%, what would be the MQL?

Because
$$RSD_{LCS} = 10\%$$
, $MQL = N \times MDL = \frac{100}{2 \times RSD_{LCS}} \times MDL = 5$ ppb,

with a precision RSD = 10% and bias %R = 90%.

In 1997 and 1998, USEPA conducted a study (Episode 6000) of variability versus concentration for a number of analytical methods. Five laboratories were employed for the analyses; each analyte and method combination was tested by one of these laboratories (USEPA July 1998). The proposed MQL procedure is evaluated using two arbitrarily selected Episode 6000 data sets of 1,1,1,2-tetrachloroethane (1112-PCA) and 1,1,1-trichloroethane (111-TCA) by Method 524.2. Figures 5 and 6 show that the SD and RSD data in the shaded areas of Tables 1 and 2 fit well to the Rocke-Lorenzato two-component model of nearly constant SD at low concentrations and proportionally increasing SD at high concentrations.

111-TCA	524.2	2	1.861	93.071	0.075	4.049
111-TCA	524.2	5	4.426	88.514	0.252	5.688
111-TCA	524.2	10	9.265	92.650	0.300	3.236
111-TCA	524.2	20	17.614	88.071	0.847	4.811
111-TCA	524.2	50	46.686	93.371	1.468	3.144
111-TCA	524.2	100	98.729	98.729	4.436	4.494
111-TCA	524.2	200	220.857	110.429	11.276	5.105

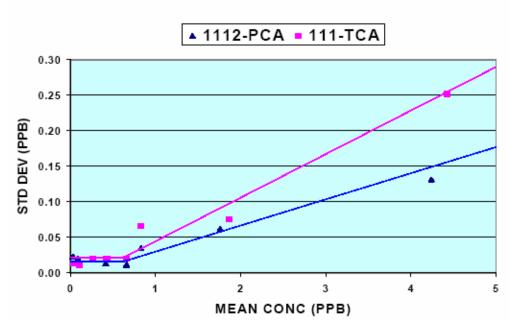

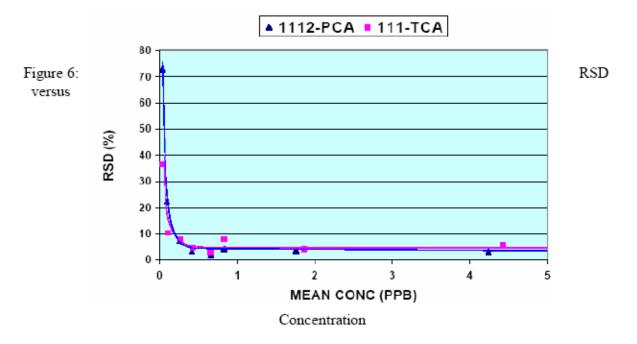

Figure 5: SD versus Concentration

Visual examination of Figure 6 shows that the MQL for 1112-PCA and 111-TCA should be around 0.5 ppb, where the data variability, RSD, starts to stabilize and stay constant at higher concentrations.

Table 3 shows a comparison of various MQLs determined based on the Episode 6000 data using common MQL procedures and the proposed MQL procedure.

	1112-PCA	111-TCA
MDL	0.05 ppb	0.06 ppb
CL _{LCS}	± 9%	±15%
$3 \times MDL$	0.15 ppb	0.18 ppb
$5 \times MDL$	0.25 ppb	0.30 ppb
$10 \times MDL$	0.50 ppb	0.60 ppb
EPA ML	0.2 ppb	0.2 ppb
ISO LOQ	0.18 ppb	0.10 ppb
Proposed MQL	0.83 ppb	0.60 ppb
(RSD / %R)	(3% / 91%)	(5% / 93%)

Table 3: Comparison of Various MQLs using USEPA Episode 6000 Data and Various Determination Procedures

The MDLs were reported by USEPA based on the procedure in 40 CFR 136 Appendix B. The LCS control limits, CLLCS, were estimated based on the SDEpisode 6000 data. The MQLs based on the proposed procedures are slightly greater than other MQLs and are the only ones reported with data on precision and bias.

QA/QC Issues

Table 3 shows that the MQL of -TCA, which has higher MDL and CLLCS, is greater than the MQL of 1112-PCA, which has lower MDL and CLLCS. This seemingly controversial situation is depicted in Figure 7, which shows higher of ± 40% gives lower MQL, compared with WLLCS of ± 20%.

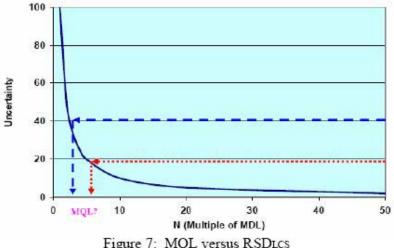

Figure 7: MQL versus RSDLCS

Normally this situation will not happen because an analyte (or a laboratory) with less uncertainty will usually have lower MDLs, which will give lower MQLs. However, if two analytes have the same MDLs but different LCS warning limits, the analyte with tighter warning limits (e.g., \pm 20%) will have a higher MQL than the other analyte with looser warning limits (e.g., \pm 40%). The data uncertainty of the analyte with a higher MQL will be less than that of the analyte with a lower MQL. Nevertheless, the analyte with a higher MQL and lower data uncertainty may be reported at a lower MQL with higher data uncertainty, but the analyte with a lower MQL and higher data uncertainty may not be reported at a higher MQL with lower data uncertainty. This controversy shows that MQL must be reported with associated precision and bias at a specified confidence level. An MQL with unknown precision and bias has limited or no practical value.

The proposed MQL procedure is based on two approximations: (1) the uncertainty within the quantitation range is constant and (2) the standard deviation $\sigma_c \approx \sqrt{2} \times \sigma_{\epsilon}$ at concentrations less than the MQL. The uncertainty over the quantitation range is not constant (dashed lines) but falls within the two arms of a hyperbola (solid lines) in Figure 8 (Mandel and Linnig 1957). The exact shape of the hyperbola arms depends on the number and distribution of calibration standards, calibration methods, etc. Approximation 1, constant uncertainty, will lead to a high biased MQL with low biased uncertainty over a small concentration range around the MQL, if the LCS concentration is at the middle of a quantitation range.

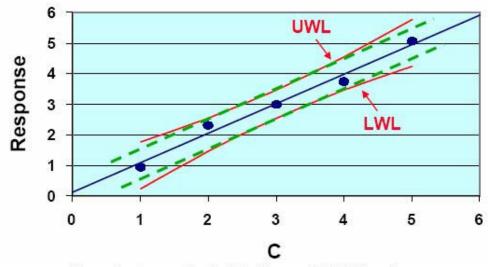

Figure 8: Assumption 1 of the Proposed MQL Procedure

The dashed line in Figure 9 is an approximation to the data uncertainty based on the Rocke-Loranzato two-component model. Approximation 2, $\sigma_c \approx \sqrt{2} \times \sigma_{\epsilon}$ at low concentrations, overestimates the data uncertainty at low concentrations and will lead to a high biased MQL with high biased uncertainty at concentrations less than the MQL. The net effect of assumptions 1 and 2 will give a high biased MQL and slightly biased uncertainty.

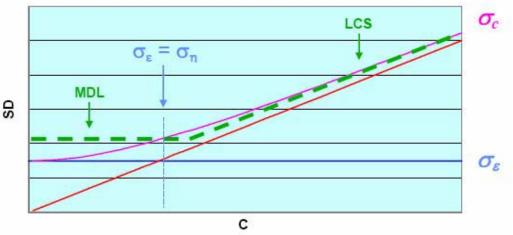

Figure 9: Assumption 2 of the Proposed MQL Procedure

Compared with N = 3.18 for the EPA ML, the N of the proposed MQL procedure is 6 and 10 for 1112-PCA and 111-TCA, respectively. Figure 10 shows that the N for 1112-PCA and 111-TCA could be set at slightly lower values and the N for ML appears too low. The data uncertainties of 1112-PCA and 111-TCA at the ML (N = 3.18) seems to be too high for reliable quantitation at low concentrations.

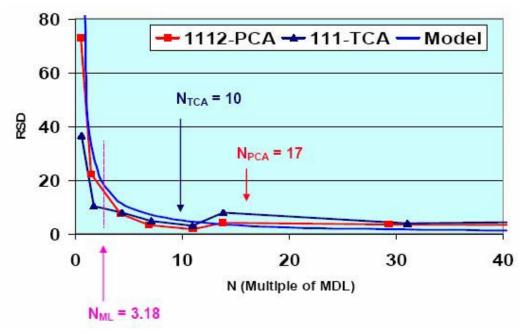

Figure 10: RSD versus N

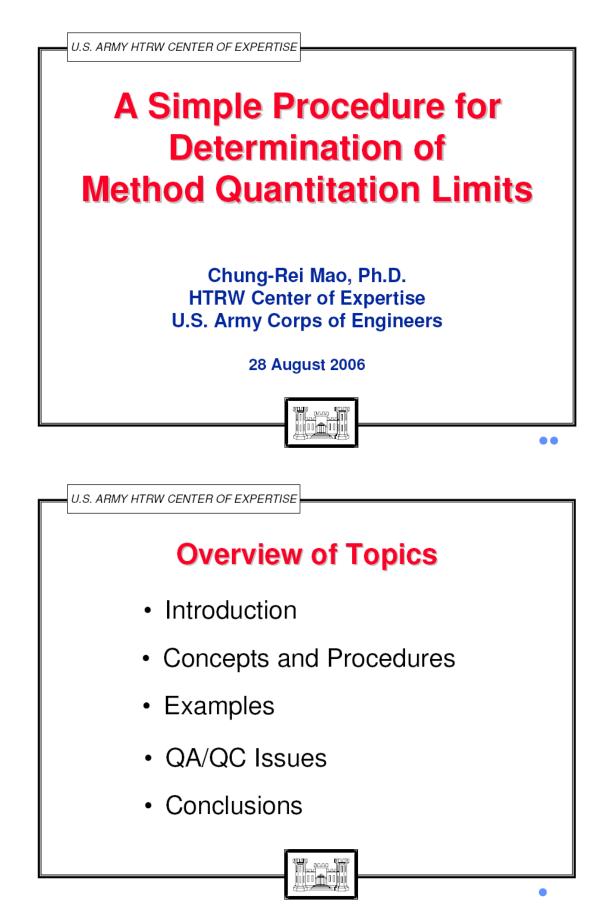

Because of the two approximations and the inherent uncertainties associated with an MDL study, it is important to verify the empirically determined MQL with an MQL verification sample (e.g., a clean matrix spiked at the MQL) on a routine basis (e.g., one per batch). The MQL verification sample shall go through all sample preparation processes and meet the same acceptance criteria of the LCS. In addition, due to the higher relative uncertainty at lower concentrations, it is recommended that MQL never be set below three times the MDL.

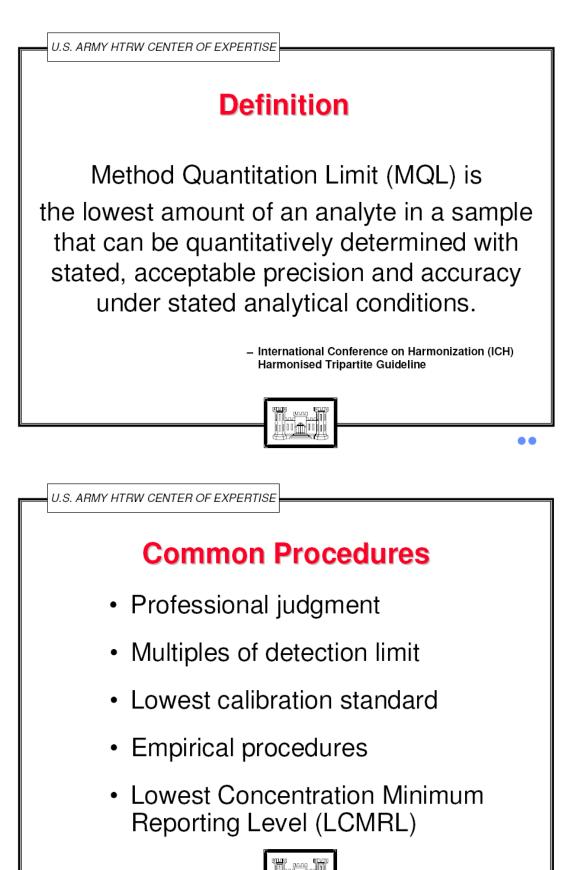

CONCLUSIONS

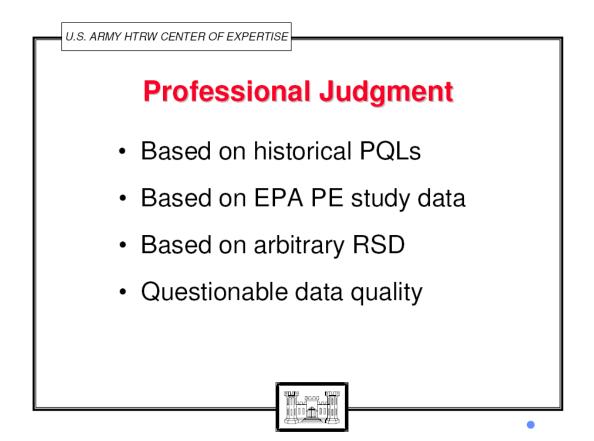

This paper presents a simple, practical, reliable, conservative, and cost effective procedure for determination of analytical MQL. This proposed procedure determines MQL based on routine, in-house performance data of MDL study and LCS control limits. The empirically determined MQL reflects a laboratory's in-house performance and has reliable precision and bias data that are often not available for MQLs determined with other common methods. To ensure reliable and comparable MQLs among laboratories, consistent procedures must be established for performing MDL study and determining LCS control limits. The empirically determined MQL shall be verified on a routine basis and reported with precision and bias data based on the control limits of LCS.

- MQL is determined based on the minimum concentration giving acceptable precision and bias
- Lacking standard procedures
- Expensive

LCMRL (Lowest Concentration Minimum Reporting Level)

- EPA procedure for single-laboratory LCMRL and MRL (PQL) of UCMR
- Lowest concentration that future recovery will fall within specified recovery range and confidence
- Based on linear regression and prediction intervals for next observation
- Complicated and expensive

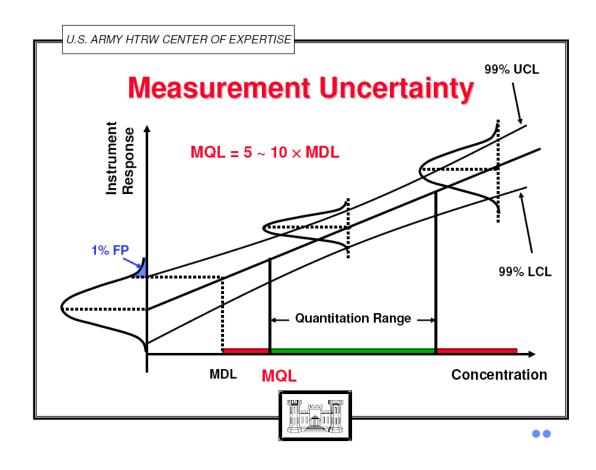

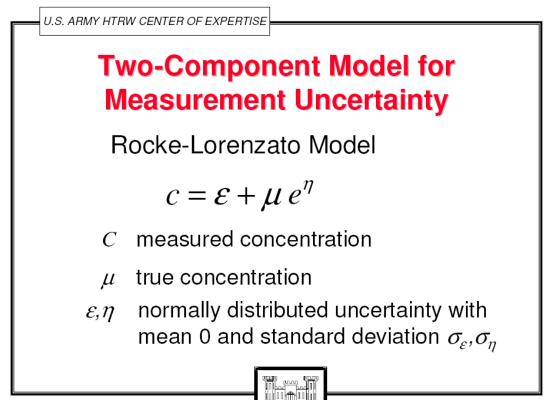

Concepts of Proposed Procedure

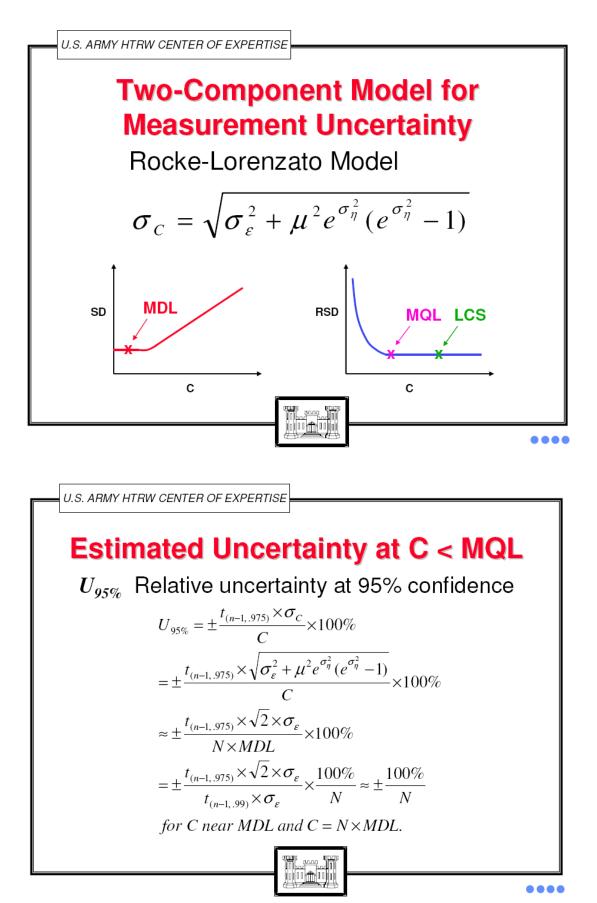

- Determine MQL based on precision versus concentration
- Determine precision based on routine QC data of MDL/MB, and LCS
- Verify MQL on a routine basis

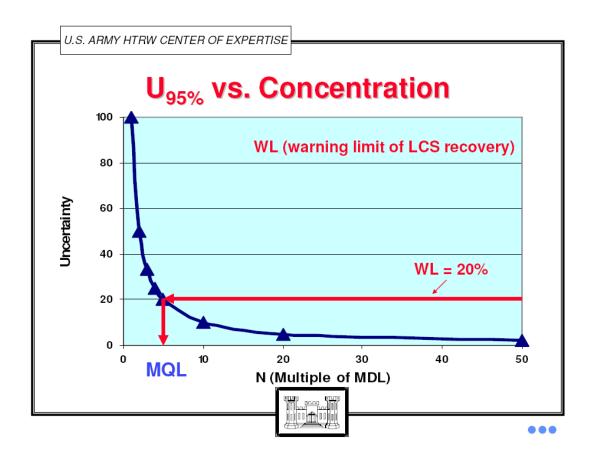

••

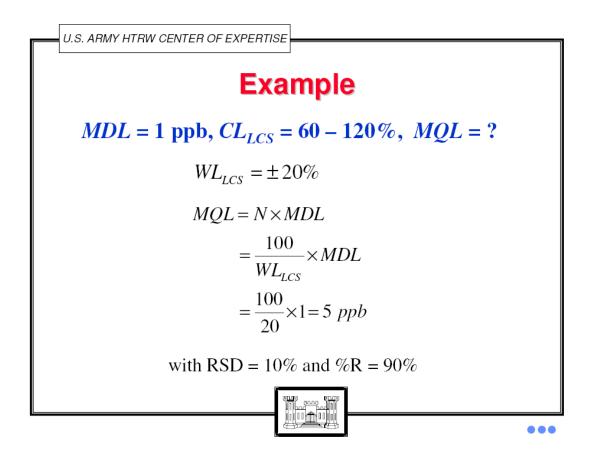

MQL Determination

MQL is established at the minimum concentration where $U_{95\%, MDL} = WL_{LCS}$

$$\frac{100\%}{N} = WL_{LCS} = \frac{t_{(n-1,.975)} \times \sigma_{LCS}}{\overline{C}_{LCS}} \approx 2 \times RSD_{LCS}\%$$
$$N = \frac{100}{WL_{LCS}} \approx \frac{100}{2 \times RSD_{LCS}}$$

 $MQL = N \times MDL$

MULTI-EVENT DETECTION LIMIT STUDY

Carter, Mark J.; Environmental Research Associates Huff, Craig; Environmental Research Associates Laferty, John; Environmental Research Associates Lowry, Jeff; Environmental Research Associates

Regulatory action levels are being set at lower concentration levels, which are challenging the ability of promulgated methods and laboratories to produce reliable data at these levels. USEPA has proposed to revise the method detection limit procedure in 40CFR136, Appendix B and has established a Technical Work Group to consider alternative procedures. A large multi-national manufacturing company with concerns about the reliability of their monitoring data at the low levels of concern engaged Environmental Resource Associates to manage a detection limit study. ERA prepared whole volume samples with analytes at concentration levels designed to challenge the ability of both methods and laboratories to detect and accurately quantify the results. Separate samples were prepared with volatile organics, trihalomethanes, semivolatiles/pesticides, carbamate pesticides, herbicides, metals, inorganic disinfection by-products, and nitrate analytes. A total of seven samples including a blank and three raw and treated water samples were prepared in preserved and unpreserved form. From three to five complete sets of samples were shipped to two U.S. and three international laboratories for analysis on defined days over a three week period. Laboratories with a demonstrated ability to report reliable results at the low levels of concern to the study were selected to participate. The laboratories used a variety of USEPA and technology based methodologies. The reliability of results at the laboratories' reporting and detection limits will be reported relative to international reporting and action levels as well as the detection limits reported in USEPA methods.

Report on a Multi-Event, Multi-Analyte, Multi-Method Detection Limit Study

Mark J. Carter, John Laferty, Craig Huff, Jeff Lowry

Environmental Resource Associates, 6000 West 54th Avenue, Arvada, CO 80002

INTRODUCTION

Regulatory action levels are being set at lower concentrations which is challenging the ability of promulgated methods and laboratories to produce reliable data at these levels. Recently, there has been a lot of recognition that the procedures used historically to determine detection limits may not represent what is routinely achievable. USEPA has proposed to revise the method detection limit procedure in 40CFR136, Appendix B and has established a Federal Advisory Committee to evaluate alternative procedures.

A large multi-national manufacturing company with concerns about the reliability of their monitoring data at low concentration levels engaged Environmental Resource Associates (ERA) to manage a study. While there were several objectives of the study, the primary one was to determine the reliability of the data that were routinely reported to them during on-going monitoring programs at the company's required reporting limits (RLs). The company was concerned about determining the potential for both false positive and negative results. While false positive results can be verified by additional monitoring, false negatives are by definition undetectable and therefore potentially seriously misleading and damaging.

ERA designed and prepared whole volume samples with analytes at concentration levels designed to challenge the ability of both methods and laboratories to detect and accurately quantify the results, both above and just below the client company's required reporting limits. Five identical sets (required to be analyzed on different days over a three week period) of seven samples were prepared including one blank and six untreated or treated drinking water-like matrix samples with aliquots containing a representative suite of volatile organic, trihalomethane, semivolatile/pesticide, Carbamate pesticide, herbicide, metal, inorganic disinfection by-product, and nitrate analytes. The analyte concentrations were randomly prepared at levels from just below to about twenty times the required reporting limits. The laboratories were told the number of samples, analytical fractions, and schedule and that they would need to employ methods to reliably achieve their client's reporting limits. The laboratories were paid by their client to run these samples as though they were from a routine monitoring program.

Laboratories with a demonstrated ability to report reliable results at the low levels of concern were selected to participate. The client has had experience with and used these laboratories for its routine monitoring programs. From three to five complete sets of samples were shipped to two U.S. and three international laboratories in Europe and Asia for analysis on defined days over a three week period. The laboratories used a variety of USEPA and/or technology-based methodologies. The identity of the samples was randomized for each of the required analysis days of the study. The reliability of results at the laboratories' reporting and detection limits will be reported relative to the client's international reporting and action levels as well as relative to the detection limits reported in USEPA methods.

STUDY DESIGN

Study Samples and Protocol

In order to address all issues of concern in the study, seven different samples were manufactured and supplied to the laboratories: Blank (sample 1); Untreated Waters, both preserved and unpreserved at two different concentration levels (samples 2-5); and two Treated Waters at different concentration levels, both preserved (samples 6 & 7). The Untreated Water samples were designed to simulate drinking waters from a municipal source and contained residual chlorine at about 1 ppm before preservation. The Treated Water samples were from a municipal water supply that was processed through a commercial water treatment system. Each of the seven samples were then split, spiked and preserved as necessary to produce eight analytical fractions: VOAs, THMs, Semivolatiles/Pesticides, Carbamates, Herbicides, Metals, Inorganic Disinfection Byproducts (DBPs), and Nitrate. Based on the analyte list and analytical methodologies in use by the study laboratories, the preparation of two identical aliquots with different preservatives was necessary for the Semivolatiles/Pesticides fraction as needed by each laboratory depending on the analytical procedure they employed. Several laboratories analyzed this fraction by several different GC, GC/MS and LC/MS methods.

A 'set' consisting of one sample each of the seven sample types for each analytical fraction was analyzed on each of five study days - days 1, 3, 7, 14 and 21 – by the two U.S. laboratories; four study days – days 3, 7, 14 and 21 by the two European laboratories; and three study days – days 7, 14 and 21 by the Asian laboratory. To allow for possible sample breakage or need for reanalysis of a sample, an extra set of samples, equivalent to the entire set of samples required on one analysis day, was included in each lab's shipment. All samples were brought to 4°C prior to packaging, placed in bubble pouches to minimize breakage and surrounded by gel ice refrigerant packs to maintain the sample temperature during shipment. Each sample was identified only by a randomly assigned number so that the laboratories could not relate the sample results from day to day.

Analytes and Concentrations

The analytes included in the study were selected from the complete list of target analytes of concern to the client company in both their U.S. and international monitoring programs. The analytes in each fraction and the concentration level of each analyte in each sample are shown in Table 1. Intentionally, the analyte concentrations in each sample was designed to be just below to no more than twenty times the client company's required reporting limits (RLs).

Three of the five participant laboratories employed USEPA 500 Series methods. All but two study analytes – Dimethoate and Malathion – are included in one or more EPA methods referenced by these three laboratories. The two European laboratories employed various separation and LC/MS as well as GC/MS methods for the Pesticide/Semivolatile, Carbamate and Herbicide analyte fractions. Other than very brief references to separation techniques and

analytical technologies, no detailed methods were provided by the European laboratories. These as well as the Asian laboratory did not analyze every analyte included in some of these fractions.

With a few exceptions, the detection limits reported in the published EPA 500 Series methods are slightly or significantly below the client's required Reporting Limits. The client's RLs were established based on monitoring and compliance requirements in the U.S. and internationally. In this regard, the exceptions of concern to this study were primarily focused on some of the analytes in the Herbicide and Pesticide/Semivolatile (e.g., see Hexachlorocyclopentadiene) fractions. However, all laboratories bid and accepted the work from the client understanding that they were required to meet the client's required reporting limits. Some laboratories charged extra to modify the methods to meet these required RLs.

Sample Preparation and Shipping

Because of the unique concentration required for each analyte in each sample, separate spiking concentrates were prepared for each study sample. The target analyte spiking concentrates were prepared in advance and analytically verified prior to use against at least one second source standard or NIST SRMs where available and reliable. Several batch manufacturing processes were used, depending on the technical requirements of each analyte group to ensure consistency and homogeneity of all like samples. In order to meet the scheduling needs of the study and realities of international shipping, all shipments had to be made on a Monday. Over 1,650 samples were prepared, preserved, labeled with a unique number, cooled to 4° C and packaged over the preceding three day period. Manufacturing was sequenced according to expected sample stability. All bottles were labeled with the client name, analytical fraction, temperature storage requirements and the sample I.D. number. In addition, a color-coded dot with the required analysis day printed on it was placed on each sample bottle and sample coolers.

Chain-of-Custody (COC) documents were generated for each laboratory for each day that each laboratory was required to analyze samples. The sample order within each fraction listed on each COC was also randomized. Therefore, while each laboratory knew that while they would be analyzing the same samples each day of the study they did not know which sample was which as the sample order was randomized for each day of the study.

ACHIEVABILITY OF DETECTION LIMITS

Volatile Organics and Trihalomethanes

The required Reporting Limits (RLs) for Volatile Organics and Trihalomethanes were consistently achievable. However, each laboratory reported results for one or more analytes in one or more samples that were either randomly or consistently biased low or high. In a few cases, there was a consistent bias in calibration, which impacted the laboratory's data by typically 15-20% but up to 50%. With a few exceptions, the laboratories correctly reported "less than" values for analytes spiked at concentrations below the required RLs. In general, the laboratories correctly detected these compounds when spiked at concentrations just above the required RLs.

Semivolatiles and Pesticides

The current analytical practices of the five laboratories do not support the conclusion that the results for most Pesticide and Semivolatile analytes at the required RLs are consistently reliable or supportable. One or more laboratories reported false positive results or Detection Limits that were above the required RLs for eight of the fifteen Pesticide and Semivolatile analytes. One or more laboratories also reported false negative results for most of the fifteen compounds in one or more samples spiked with the Pesticide and Semivolatile analytes in the samples where the true concentrations were up to twenty times the required RLs. Both of these issues demonstrate that the true DLs of these laboratories using their current practices for many of the Pesticide and Semivolatile compounds are higher than they reported as well as the client's required Reporting Limits. All laboratories to a lesser or greater extent, reported results for some Pesticide and Semivolatile compounds that were consistently biased, either high or low and/or were highly variable at all concentration levels. While potentially achievable under just the right conditions, it is reasonable to conclude that the detection limits reported in the EPA 500 Series methods for these analytes is not reliably achievable.

Carbamates

The results from the three best performing laboratories showed very good and consistent recoveries of the Carbamate Pesticides but still included a few false negatives at concentrations just above the required RLs. The DLs reported by one laboratory for Carbamates were five times the required RLs resulting in many false negatives in the samples spiked at low concentrations. The fifth laboratory reported false positives for three Carbamates in one blank sample and results in general that were highly variable with many false negatives calling into question the validity of all their RLs.

Herbicides

The results from the two best performing laboratories showed good recoveries of the Herbicides with virtually no false negatives at concentrations above the required RLs. The other laboratories reported DLs that were too high compared to the required RLs or had results so variable that it is not possible to come to any conclusion from their data about the general achievability of the required RLs. While two of the laboratories reliably achieved the required RLs, three laboratories clearly did not, indicating that possibly this method is not rugged in other than the most careful and capable laboratory.

Metals

One laboratory consistently reported very accurate results for all metals and reported no false positives or negatives. The other four laboratories reported false positives in some blanks and DLs for one to three metals that were above the required RLs. This caused a number of these laboratories to report false negatives at concentrations above the required RLs. While the technology exists for laboratories to meet the required RLs for metals, the current practices of most of these laboratories are such that these limits are not being consistently being met.

Inorganic Disinfection By-Products

Only three laboratories performed analyses for the three Inorganic Disinfection By-Product (DBP) analytes. Other than one false positive in one blank sample, the three laboratories reported consistently accurate results for the three Inorganic DBP analytes in all samples. It is appropriate to conclude that the RLs for Inorganic DBP analytes are routinely achievable.

Nitrate

Only one laboratory reported results for Nitrate that were consistently accurate at all concentration levels. Two other laboratories reported DLs above the required RLs, which made the evaluation of the reliability of results at this level impossible to determine. While not always reporting false negatives, the other two laboratories' results were consistently biased low. While the technology and laboratory procedures exist for laboratories to meet the required RLs for Nitrate, the practices of all but one laboratory in this study is such that these limits are not being met routinely.

DATA QUALITY ISSUES

In addition to the issues discussed above, most laboratories had one or more data quality issues that are important to address. In routine monitoring situations, most of these problems would not be detectable. What made the detection of the errors possible is the fact that the analyte true values were known and that the laboratories analyzed the same samples from three to five times during the study, albeit in a single blind manner. These errors came from improper calibration, mixed up sample identifications, significant random errors during sample preparation and/or analysis. A few examples are:

Inadequate Reporting Limits

Even after being directed and agreeing to use methods that could achieve the required RLs, every laboratory reported DLs for one to thirteen analytes that were from two to twenty times the client's required reporting limits. This made it difficult or impossible to assess the technical achievability of the required RLs for some analytes.

Misidentification of Samples

One laboratory misreported the identity and therefore results of all analytes in four samples analyzed on one day of the study for the Pesticides fraction. Another laboratory misreported the identity and therefore results for all analytes in four Herbicides samples analyzed on one day of the study. A third laboratory switched all results for two Herbicide samples analyzed on one day of the study. Once ERA received the results and performed simple pattern recognition, the switching of results became apparent. Without inappropriate prompting, the laboratories were able to sort out and correct these data reporting problems. There were a number of other instances of apparent sample misidentification or data mix-up that the laboratories could not resolve without inappropriate prompting. In the vast majority of routine monitoring situations, the switching of sample identifications and misreporting of results would not be detectable. This was one of the most surprising and least anticipated problems that occurred during the study.

Systematic Calibration Errors

One laboratory initially reported results for all Volatile Organic and Trihalomethane compounds that were too high by an order of magnitude. After being appropriately prompted by ERA, the laboratory determined that they made an error that was caused by their purchase and use of a calibration standard that was an order of magnitude lower in concentration than they thought. The problem, if not detected and questioned, would have resulted in all of the data analyzed using these standards being in error by a factor of ten. While the immediate problem was resolved, this situation raised a number of questions about the routine quality control practices of this highly regarded international laboratory.

Un-communicated Study Instructions

While the project manager of one laboratory was informed that separate samples would be provided for analysis of Volatile Organic and Trihalomethane compounds, the laboratory initially reported all results for the Trihalomethane fraction out of the Volatile Organics fraction as "Not Detected." Upon appropriate prompting, the laboratory recognized the reporting error and reported the corrected and ultimately accurate results for these analytes. This situation illustrates the importance of communication and follow-up to ensure the proper reporting of data from non-routine analysis requests.

ASSESSMENT OF OVERALL DATA QUALITY

As one assessment of data quality, all individual results that were reported as a false negative or outside of 50-150% of the true value were identified. Using these criteria, the best overall performing laboratory had almost eight percent of their reported results identified as potentially problematic. For each laboratory, the mean recovery for each analyte for all samples was calculated. Based on ERA's historical Performance Acceptance Limits, the best laboratory had nine of forty-six mean analyte recoveries identified as significantly biased. The other laboratories had from fifteen to twenty-one analytes with a consistent notable bias. Addressing only mean recoveries can be misleading without considering the variability of the data. The analytes in each sample that had mean RSDs above 40% were identified. The best laboratory had only four analytes with RSDs above 40% for all samples they analyzed. The poorest laboratory in this regard had thirteen of forty-two analytes with mean RSDs above 40%.

NOTABLE METHOD ISSUE

One laboratory analyzed five of the Pesticide analytes by both GC/MS (525) and GC (505) techniques. The mean recoveries for these analytes using GC/MS ranged from 38-162% and using GC from 86-111%. The RSDs using GC/MS ranged from 23-47% and using GC from 9-20%. While it's hard to deny the efficiency of the GC/MS technique in producing simultaneous results for a wide suite of analytes, clearly the GC technique produced the most consistently accurate recoveries and best precision.

BEST PERFORMANCE HARD TO DEFINE

In order to determine if there were any consistent measures of a laboratory's ability to analyze samples at the low levels required by the client, the data were ranked by fraction according to mean recovery and RSD. Considering the composite recovery/RSD ranking, one laboratory performed the best on the Volatile Organic, Trihalomethane and Inorganic Disinfection-By Products analytical fractions. While this same laboratory reported the best results for Dimethoate using a solid-phase extraction-LC/MS method, an analyte the analysis of which confounded all other laboratories, their composite performance for the rest of the Pesticides/SVOAs was second to worst among all laboratories. Their results for the Carbamate and Herbicide fractions were among the most biased and highly variable among all laboratories' data. It is not clear if the issue is from calibration and /or sample preparation problems.

Another laboratory reported the best results by far among all laboratories for the Herbicide fraction, the worst by far for the Pesticides and Semivolatile fractions and in the middle for the other organic analyte fractions. In addition, this laboratory's Metals and Nitrate data were either the most variable or least accurate in the study. The laboratory's use of atomic absorption techniques for Arsenic, Cadmium and Lead demonstrated the inappropriateness of this approved method to analyze samples at the low Reporting Limits required in this study.

Overall, the best performing laboratory reported the best results for only the Carbamate analyte fraction. The only exception to their otherwise good to excellent performance was for the metals analyte fraction, which had low and high biased results, respectively, for iron and lead.

CONCLUSION

While the results of this study might suggest that the participant laboratories have a few or many analytical problems, the fact is that the samples were designed to provide a stern test of both the laboratories and the methods they used. The concentration of the lowest level study standards was often more than an order of magnitude lower than the corresponding NELAC PT standards for many of the analytes. While it can be concluded that the published detection limits for the Volatile Organic, Trihalomethane, Metal and Inorganic analyte fractions are generally routinely achievable, the study supports the contrary conclusion for many if not most of the Pesticide, Semivolatile, Carbamate and Herbicide analyte fractions. The current effort by EPA to improve and standardize the protocol to quantitatively determine detection limits will help ensure the reliability and realism of low level analytical results.

Report on a Multi-Analyte, Multi-Method Detection Limit Study

Mark J. Carter, John Laferty, Craig Huff and Jeff Lowry Environmental Resource Associates August 28, 2006

Study Sponsor

- Fortune 500 company with multinational monitoring requirements.
 - Regulatory limits low & going lower.
 - Established required lab reporting limits (RLs).
 - A challenge for labs and methods to produce reliable data at these low levels.

Multiple Study Objectives

- Determine data reliability.
 - At concentration levels from just below to ≤20-30X required RLs.
 - False positives can be verified by additional monitoring.
 - False negatives by definition are undetectable and a greater concern.
- Study also designed to look at preservation issues at these levels.

Laboratory Participants

- Five laboratories selected with proven capability to analyze samples at low levels.
 - Two U.S., two European & one Asian.
- Intent to challenge methods and assess routine data quality in samples with analytes at low concentration levels.

Seven Study Samples

- One blank.
- Two raw waters.
 - Each split with preserved and unpreserved fractions prepared.
- Two treated waters.
 - Each with only preserved fractions prepared.

Each Sample Had Nine Separate Fractions

- Volatile Organics (6 analytes)
- Trihalomethanes (4)
- Pesticides/Semivolatiles (15) one fraction each for GC and GC/MS & LC/MS
- Carbamates (4)
- Herbicides (6)
- Metals (7)
- Inorganic Disinfection By-Products (3)
- Nitrate (1)

Sample Designs

- Whole volume samples.
- Analytes selected from client's list.
- Analyte concentrations randomly but logically set.
- Generally higher levels in raw waters.
- Levels in treated waters just above & below RLs.
- Compromises made in sample bottles, volumes and preservatives.

Laboratory Communication

- Labs paid to run as routine samples.
 - Client did not dictate methods.
 - Requirement to achieve client's RLs.

• Labs told:

- Number and type of samples.
- Analytical fractions and target analytes latter reluctantly.
- Approx. concentration range.
- Schedule.

Sample Preparation

- Separate spiking stocks prepared for each fraction in each sample.
 - Verified against 2nd source standards.
- Final sample preparation occurred from Saturday am Monday pm, staged in order of stability.
 - Different prep. techniques used to ensure consistency & homogeneity of all samples.
 - Over 1,650 whole-volume sample fractions prepared.

Study Protocols

- Random sample numbers assigned & order scrambled for each day's run.
- An extra bottle of each fraction was supplied for problems.
- Samples/shipping containers coded for I.D. of each day's samples.
- Samples chilled, packed with blue ice, palletized and air shipped for 1-3 day delivery, depending on location.
- Labs to report data after each day's run.

Analysis Schedule

- Six identical sets to US labs.
 Analyzed on days 1, 3, 7, 14 & 21.
- Five sets to European labs.
 - Analyzed on days 3, 7, 14 & 21.
- Four sets to Asian lab.
 - Analyzed on days 7, 14 & 21.
 - Later schedule due to customs issues.

Method Summary

- US & Asian labs EPA 500 methods.
 - One lab used both GC & GC/MS methods for pesticides.
- European labs referenced technologybased methods – few details.
 - Multiple methods per analyte group.
 - Reliance on LC/MS as well as GC/MS.
- No comforting definition of how labs (or EPA?) determined DLs or RLs.

Analytical Methods

- VOAs & THMs.
 - 524.2 (Purge/Trap-GC/MS).
 - Headspace-GC/MS & -GC/ECD (THMs).
- Pesticides/Semivolatiles.
 - 525.2 (Liquid/Solid Extraction-GC/MS).
 - Pesticides by 505 (Microextraction-GC).
 - SPE-GC/MS & -LC/MS, SBSE-GC/MS.
- Carbamates
 - 531.1 (Direct Inject.-HPLC).
 - SPE-LC/MS.

Analytical Methods

- Herbicides
 - 515.4 (Liq.-Liq. Microextract.-GC/EC).
 - 515.3 (Liq.-Liq. Extraction-GC/EC).
 - Direct inject & SPE-LC/MS; SBSE-GC/MS.
- Metals
 - 200.8 (ICP/MS), Optical ICP, Hydride & Furnace AA.
- Inorganic DBPs
 - 300.1 (IC); 317 (post-column IC).
- Nitrate
 - 300 (IC); 353.2 (Colorimetric).

Evaluation of Problematic Data

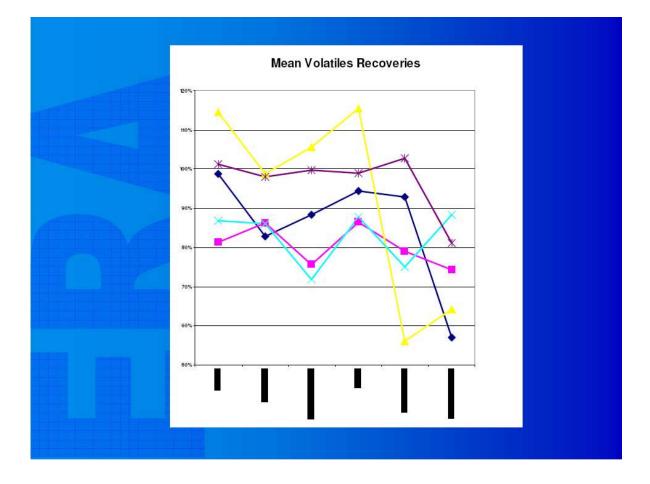

- DLs or RLs too high.
 - Issue for 1-13 analytes/lab.
- False negatives (55%) or positives (45%).
- Result outside of 50-150% of true value.
 - No magic to this range.
- Problematic data by lab ranged from 10-21%.
 - Performance varied widely by fraction.

% Problematic Study Data by Analytical Fraction

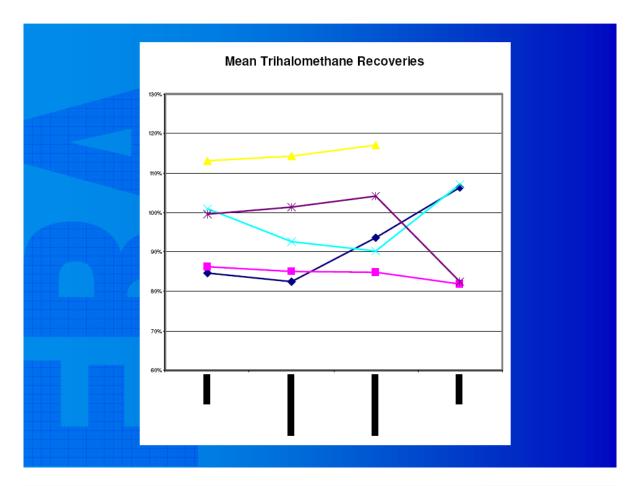

VOAs	4.4%
THMs	3.3%
Pests/SVOCs	18.4%
Carbamates	25.2%
Herbicides	24.6%
Metals	13.5%
DBPs	0.5%
Nitrate	27.6%

VOAs & THMs

- Results generally reliable at required RLs.
- In a few cases, consistent bias by 15-20%, but up to almost 50%.
- One lab initially reported all VOAs & THMs too high by 10X.

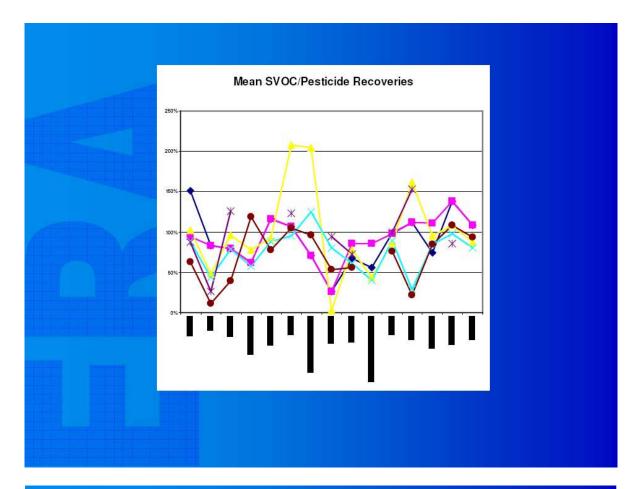

22nd Annual National Environmental Monitoring Conference

Pesticides & SVOCs

- One or more labs reported false negs. for most analytes in one or more samples at concs. up to 20X RLs.
- Results highly variable which does not support conclusion that RLs are generally achievable.
- For pesticides, GC data more accurate and precise than GC/MS.
 - Mean recoveries for GC (86-111%) & GC/MS (38-162%).
 - Mean RSDs for GC (9-20%) & GC/MS (23-47%).

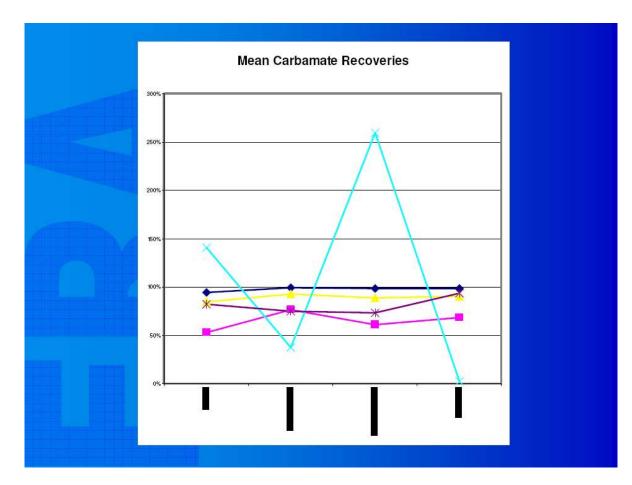

22nd Annual National Environmental Monitoring Conference

Carbamates

- Three best labs had good & consistent recoveries.
 - Still a few false negatives.
- Other two labs' results.
 - DLs too high, both false negs. & pos.
 - Results highly variable.
- Different labs using LC & LC/MS methods had good data.
- RLs achievable, but not consistently.

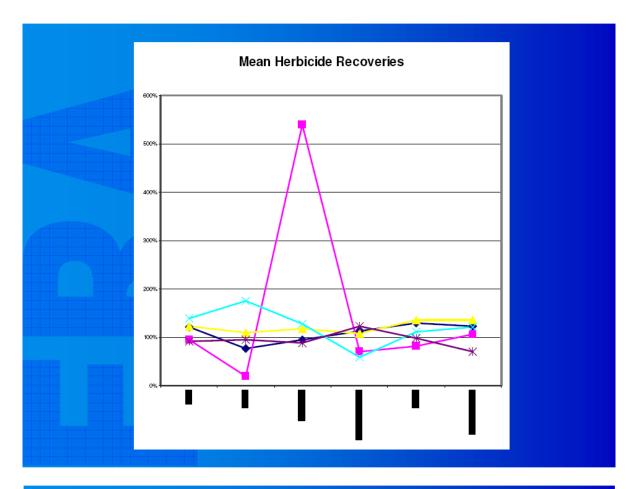

22nd Annual National Environmental Monitoring Conference

Herbicides

- Two labs.
 - Good recoveries & no false negatives.
- Other three labs.
 - Some DLs too high, false negs. & pos. & results quite variable.
- Methods not rugged.
- RLs achievable, but certainly not consistently.

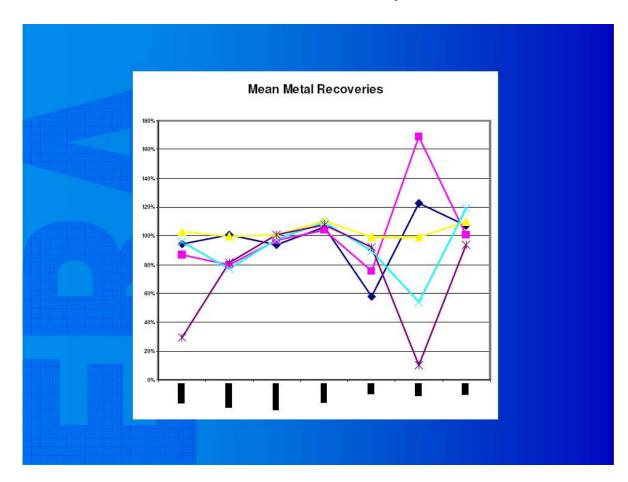

22nd Annual National Environmental Monitoring Conference

Metals

- One lab's results quite accurate & precise.
 - Mean recovery (99-111%) and mean RSDs (1-5%).
- Other labs false pos. in one or more blanks.
- DLs reported above required RLs.
- ICP/MS clearly best, but contamination an issue.
- Data from AA methods problematic.
- RLs achievable; but not consistently achieved.

22nd Annual National Environmental Monitoring Conference

FALSE-FALSE POSITIVES

Dechant, Gary; Analytical Quality Associates, Inc.

Among the greatest challenges that exist in the environmental industry today are those associated with defining, measuring near, and regulating near the detection limit of an analytical technique. Of specific concern are detects that cannot be reliably confirmed and the associated reaction to these detects. The term "false-false positive" is used for this occurrence and is defined as a result that is a true positive value above the detection limit but that cannot be confirmed with any degree of confidence and, therefore, is routinely classified as a false positive.

Two of the more misused and misunderstood statements concerning detection of an analyte are (1) We are 95% confident that the measured analyte is a detect, and (2) We are 95% confident that we have a detectable concentration in the sample. While these two statements appear similar, they are very different, and that difference defines the realm of the false-false positive.

To understand the difference between these two statements, one must look at the definition of a detection. For the purpose of comparison, a detect is considered to be a result at or above the concentration at which one is 95% confident the value is not zero. To determine this concentration, methods such as those described in 40 CFR 136, Protection of Environment: Guidelines Establishing Test Procedures for the Analysis of Pollutants, are used. The "detection limit" is defined as the concentration at which there is only a 5% probability of a positive result being derived from a zero concentration true value. Results above this value are considered to be detects at the 95% confidence level.

While this definition supports the first statement, it should be noted that this is a pass/fail test for the comparison of a result against a reference value, the MDL, and it implies only that this specific result derives from a non-zero concentration.

The second statement, "We are 95% confident that we have a detectable concentration in the sample," is a predictive statement implying that given a large number of samples, the laboratory will measure a value greater than the detection limit 95% of the time. To fully understand how this works, one must look at the response distribution of a zero-concentration measurement used to determine the detection limit. Under ideal conditions, this distribution is normal and has an average of zero, and the value at two standard deviations of the response variability above zero is the detection limit. At zero concentration, only 2.5% of a large number of measurements will be greater than the detection limit. As the true value in the sample increases, the actual probability of the result being greater than the detection limit increases, and the probability of the result being less than the detection limit decreases. As the distribution moves up the true concentration axis, one finds that when the true value of the sample is exactly equal to the detection limit, the probability of the measured result being greater than the detection limit is 50% and the probability of the result being less than the detection limit is 50%. At this concentration, regardless of how many samples are analyzed, there is still only a 50% chance of measuring a value greater than the detection limit. If a sample is split with the regulator, there is a 50% chance that one laboratory will show a detect and the other laboratory will show a non-detect. Upon re-sampling, there will be a 50% chance that the detect will confirm and a 50% chance that the detect will not confirm. Regardless of how many times a sample is taken, for a large population, the distribution of detects and non-detects will be 50% of each centered on the detection limit. Values at these concentrations cannot reliably be used for decision-making.

As this does not meet the criterion of the second statement, one must continue to move the distribution up the true value axis until the point where 95% of all results in a large population, will be greater than the detection limit it reached. That is the point at which the true value is equal to two standard deviations above the detection limit. This point is the minimum concentration value at which it can be predicted that 95% of the laboratory results will be greater than the MDL.

While the laboratories may be required to report down to the detection limit, the data user in the environmental community cannot make sound decisions based on single measurements whose results are between the MDL and two times the MDL. One must also be cognizant of the fact that for true values at or slightly above the MDL concentration, even under extensive research and re-sampling, it is highly probable that whether the true value is above or below the detection limit will be unable to be determined.

In order to better facilitate the appropriate use of data in this category, it is proposed that a new data validation flag be used to identify data that may be able to support decision making, but by itself should not be used in decision making.

Understanding False Positives and False-False Positives

Gary Dechant

Analytical Quality Associates, Inc.

ABSTRACT

In the environmental laboratory, analytical results can sometimes be misleading. One particular case of this is where the analytical result falls near the method detection limit. True values will often be categorized as false positives when they are actually true values, or false-false positives. In order to determine where the potential for false-false positives lies, one must first understand the difference between a "detect" and a "detectable concentration." In order to do so, it is important to know the definition of method detection limit and to review the response distribution at zero concentration used to determine the method detection limit. Because the false-false positive range is equal to the analytical uncertainty of the measurement, it can be quantified using an equation given in *Quantifying Uncertainty in Analytical Measurement* (EURACHEM/CITAC 2000), and the probability that the sample result will fall within that range can be determined. Although less than one percent of laboratory results fall into the false-false positive range, the impact of this occurrence can be significant. It is important to understand the false-false positive and its impact on the environmental community, and once understood, to develop a system that will effectively deal with it.

INTRODUCTION

Among the greatest challenges that exist in the environmental industry today are those associated with defining, measuring near, and regulating near the detection limit of an analytical technique. Of specific concern are detects that cannot reliably be confirmed and the associated reaction to these detects. The term "false-false positive" is used for this occurrence and is defined as a result that is a true positive value above the detection limit but that cannot be confirmed with any degree of confidence and, therefore, is routinely classified as a false positive.

Of particular concern are the common responses to measured values that fall within this classification. These responses include re-analysis, re-sampling, and other additional investigations that are generally costly and time consuming. Even after expending more resources investigating these results, one cannot definitively determine whether or not the sample or sample location has a detectable concentration of analyte. In fact, multiple sampling and replicate analyses of these samples can yield results that support opposite conclusions.

It is important to fully understand where the false-false positive originates from and the impacts it has on the environmental community. From there, a commonly accepted industry standard practice can be adopted to lessen the impact of the false-false positive.

UNDERSTANDING THE FALSE-FALSE POSITIVE

Detect Versus Detectable Concentration

Two of the more misused and misunderstood statements concerning detection of an analyte are (1) We are 98% confident that the measured analyte is greater than zero; that is, the result is a detect, and (2) We are 98% confident that we have a detectable concentration in the sample. While these two statements appear similar, they are very different, and that difference defines the realm of the false-false positive.

To understand the difference between these two statements, one must look at the definition of detection. The currently accepted definition of a detect is considered to be a result at or above the concentration at which one is 98% confident the value is not zero. To determine this concentration, methods such as those described in 40 CFR 136, Protection of Environment: Guidelines Establishing Test Procedures for the Analysis of Pollutants, are used. This defines the detection limit as three standard deviations above zero of the variation, or uncertainty, of the signal or response. The "detection limit" is the concentration at which there is only a one percent probability of a positive result being derived from a zero concentration true value. Results above this value are considered to be detects at the 98% confidence level. While this definition supports the first statement, it should be noted that this is a pass/fail test for the comparison of a result against a reference value, the method detection limit (MDL), and it implies only that this specific result derives from a non-zero concentration.

The second statement, "we are 98% confident that we have a detectable concentration in the sample," is a predictive statement implying that given a large number of samples, the laboratory will measure a value greater than the detection limit 98% of the time. To fully understand how this works, one must look at the response distribution of a zero-concentration measurement used to determine the detection limit.

Response Distributions

Under ideal conditions, the response distribution of a zero-concentration measurement is normal and has an average of zero (Figure 1), and the value at three standard deviations of the response uncertainty above zero is defined to be the detection limit. At zero concentration, only one percent of a large number of measurements will have values greater than the detection limit. As the true concentration in the sample increases, the actual probability of the result being greater than the detection limit increases, and the probability of the result being less than the detection limit decreases. As the distribution moves up the true concentration axis, one finds that when the true concentration of the sample is exactly equal to the detection limit, the probability of the result being greater than the detection limit is 50% and the probability of the result being less than the detection limit is 50%.

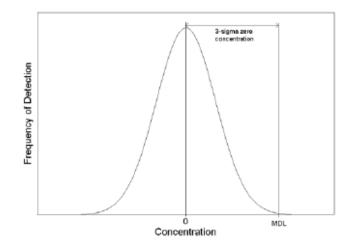

Figure 1: MDL Normal Distribution

At concentrations near the MDL, regardless of how many samples are analyzed, there is still only a 50% chance of measuring a value greater than the detection limit. If a sample is split between two laboratories, there is a 50% chance that one laboratory will show a detect and the other laboratory will show a non-detect. Upon re-sampling, there will be a 50% chance that any detect will confirm and a 50% chance that a detect will not confirm. Regardless of how many times a sample is taken, for a large population, the distribution of detects and non-detects will normally be distributed around the MDL, with 50% of the results detects and 50% of the results non-detects (Figure 2). Therefore, values at these concentrations cannot reliably be used for decision-making. Additionally, re-analysis, re-sampling, and other investigations resulting from any unreliable results will most likely be inconclusive and not at all cost effective.

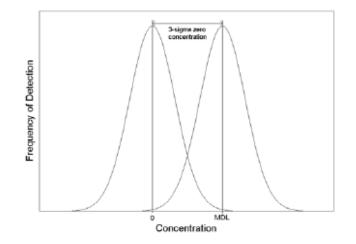

Figure 2: Distribution around the MDL

As this distribution does not meet the criterion of the second statement, one must continue to move up the true concentration axis until the point at which 98% of all results in a large population will be greater than the detection limit is reached. That is, the point at which the true concentration is equal to three standard deviations above the detection limit (Figure 3) is reached. That point is the minimum concentration value at which it can be predicted that 98% of the laboratory results will be greater than the MDL.

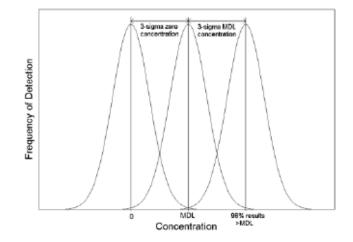

Figure 3: Distribution at Three Standard Deviations above the Detection Limit

Other Factors

Random problems associated with laboratory blanks and general laboratory contamination also exacerbate the issue of false-false positives. Just as with a sample that has a true concentration at the MDL, a blank with a true concentration at the MDL will show up as a low level detection in only 50% of a set of measurements; however, 50% of the samples that have blank or laboratory contamination at this level will have detections identified. In this case, positive sample results with related non-detect blank results will be inaccurately reported as positives.

The Uncertainty

One practice that has been used to minimize the problems with "false positives" is to shift the detect or non-detect decision point to above the MDL and into a range where the measurement is more reliable. While this would appear to be a good idea on the surface, it actually makes the situation worse.

The false-false positive range is actually the three-sigma uncertainty of the value. In keeping with the definition of MDL, the three-sigma uncertainty at the MDL is almost equal to the MDL. Therefore, the false-false positive range above the MDL is approximately equal to the MDL. Because the false-false positive range is equal to the three sigma analytical uncertainty of the measurement, the false-false positive range will increase as the true concentration is increased.

To estimate the uncertainty, a method based on Section E.4 of *Quantifying Uncertainty in Analytical Measurement* (EURACHEM/CITAC 2000) is used. This approach asserts that although general analytical chemical measurements have, over a large range, a dominant uncertainty that can be approximated using a proportionality constant, it is more appropriate to use a fixed uncertainty at low concentrations near the detection limit. This model was chosen because it is a simple, straightforward approach and the values required are readily available. This principle can be expressed using the general equation:

$$Uc = \sqrt{S_0^2 + (S_1 \times C)^2}$$

Where:

Uc = Total uncertainty at the 68% confidence level (one sigma)

So = Fixed uncertainty

 $S_1 = Proportionality constant$

C = Measured concentration

From this equation, S_0 is the uncertainty associated with a zero concentration sample. According to the definition of MDL given in 40 CFR 136, the MDL is three times the uncertainty of a sample with zero concentration. Assuming a relatively normal distribution around zero, S_0 can be estimated as MDL/3.

The proportionality constant (S_1) is the relative uncertainty of the measurement as a function of concentration. A laboratory control sample (LCS) is generally defined as a known matrix spiked with analytes representative of the target analytes at known concentrations that is taken through the same analytical process as the samples. The variability of the LCS is an estimate of the uncertainty of the LCS at that concentration, and the relative variability at one sigma can be used to estimate S_1 if the concentration of the LCS is very large compared to the MDL; that is, the contribution of the variability from the constant S_0 is small relative to that from S_1^*C . For comparative purposes, the ideal matrix of an aqueous LCS is used.

Both the MDL and the relative variability of the LCS are values readily available in a laboratory database.

Using this model, the false-false positive range, as defined by the three sigma uncertainty, at the MDL is:

$$FFR = 3 \times \sqrt{\left(\frac{MDL}{3}\right)^2 + (RU_{LCS} \times MDL)^2}$$

Where:

FFR = False-false positive rangeMDL/3 = Fixed uncertainty $RU_{LCS} = Relative variability of the LCS at one sigma$ MDL = Concentration of the MDL For a metals analysis by inductively coupled plasma-atomic emission spectroscopy, RU_{LCS} may be somewhere around 3%, or about 0.03. Therefore,

$$FFR = 3 \times \sqrt{\left(\frac{MDL}{3}\right)^2 + (0.03 \times MDL)^2}$$

 $FFR \cong MDL$

If the detect/non-detect decision point is raised to 10 times the MDL, then:

$$FFR = 3 \times \sqrt{\left(\frac{MDL}{3}\right)^2 + (0.03 \times 10 \times MDL)^2}$$

Given that the decision point is now at a more reliable concentration, the increase in that falsefalse positive range may be considered acceptable. However, when this same model is applied to compounds where the RU_{LCS} may be as high as 20%, the model now becomes the following:

$$FFR = 3 \times \sqrt{\left(\frac{MDL}{3}\right)^2 + (0.2 \times MDL)^2}$$

$$FFR \cong 1.17 \times MDL$$

And at 10 times the MDL,

$$FFR = 3 \times \sqrt{\left(\frac{MDL}{3}\right)^2 + (0.2 \times 10 \times MDL)^2}$$

$$FFR \cong 6.08 \times MDL$$

The Probability

The concentration range of the false-false positive range is small; therefore, the probability that a sample result will fall within that range is expected to be very small for analyses such as metals, where the variability is also small. However, this may not be the case for analyses that exhibit a large variability. A quick review of ground water data for one fairly common site over two years resulted in the following: Out of a total of ~40,000 analytical results, approximately 500 were reported as detects, and of the detects, approximately 250, or about 0.6% of the results, were detects between the MDL and two times the MDL.

THE IMPACT OF FALSE-FALSE POSITIVES

Although less than one percent of the results fall into the false-false positive range, the impact of this occurrence can be significant.

For results associated with a split sampling event, there could be as much as a 50% chance that any decisions made using the two results from the split would be exactly opposite. That is, a decision that the analyte is present would be made based on one result, and a decision that the analyte is absent would be based on the other result. This could potentially cause many problems for decisions made regarding regulatory compliance, including the added expense of re-analysis and/or re-sampling.

When compared against historical data, a false-false positive result could be found to be inconsistent, requiring the laboratory to perform re-analysis. The laboratory would then incur a loss of revenue for a quick response re-analysis. In addition, there is a high probability that the re-analysis will produce a non-detect purely by random chance, and although the end result would be the desired result (a non-detect), it may not be the most accurate result.

If the re-analysis produced another detect, re-sampling may be required to verify the result. In this case, in addition to the funds expended for the routine analysis and re-analysis of the sample, there is an additional cost to acquire another sample and have that sample analyzed. And once again, there is a high probability that the re-sampling and re-analysis will result in a non-detect based purely on chance.

CONCLUSIONS

When a detect/non-detect decision point is defined, any result above that value is a detect. However, a detect does not necessarily identify a detectable concentration. Detects between any detect/non-detect decision point and three standard deviations of the uncertainty in the measurement above that point are real detects but may not be reliably reproduced. While the laboratories may be required to report down to the MDL, the data user in the environmental community cannot make sound decisions based on single measurements whose results are between the MDL and three standard deviations above the MDL (that is, two times the MDL). One must also be cognizant of the fact that for true values at or slightly above the MDL concentration, even under extensive research and re-sampling, it is highly probable that whether the true value is above or below the detection limit will be unable to be determined. Decisions must be made on detectable concentrations, and a detect that cannot be reliably reproduced can only be used as part of a data set and not as a stand-alone data point.

The amount of data that is included within the false-false positive range is small; however, the potential ramifications and cost to the environmental community of mishandling this data is significant enough that the data within this range needs to be specifically identified. In order to better facilitate the appropriate use of data in this category, a new data validation flag should be used to identify this data. This flag should specifically identify data that is not reproducible and that should not be used by itself for decision-making. In addition, it should specifically state that

further investigations are not recommended. A commonly accepted industry standard practice of not responding to these types of detects should be established so that any data challenged by nontechnical groups such as concerned citizen groups, the general public, or any other external entity can be justified based on this accepted practice.

PLENARY SESSION

Special Panel: The Health, Depth, and Breadth of the Environmental Monitoring Industry

The Health, Depth and Breath of Environmental Monitoring in the United States

- A Commercial Laboratory Perspective -

Robert K. Wyeth General Manager Severn Trent Laboratories, Inc.

Health

...whether the U.S. environmental testing industry is delivering the quality of data needed?

Health as Data Quality

Simple "yes" or "no" answer can't be given!
Sometimes and from some commercial labs

- All (most) labs strive to provide data that meets the needs of its intended use
- Some labs (fortunately only a few) can't be trusted to provide quality data.

How do we measure Quality?

- Accreditation
- Audits
- Establish DQO's
 - Precision
 - Accuracy
 - Representativeness
 - Completeness
 - Sensitivity
- Blind Duplicates/Spikes
- Data Validation

...but what are we measuring?

- Accreditation doesn't assure performance but it's a good start!
 - Reportedly there are more than 10,000 labs in the US
 - Approximately 50% are estimated to be "commercial"
 - Some but not all are accredited
 - Those that aren't don't want to be!
 - NELAC and State accreditations are widely variable and inconsistent in application (and in competence)
- The choice of a laboratory based solely on accreditation is like measuring competence based upon a person holding a degree.

...but what are we measuring?

Audits

- Conducted independent of accreditation or certification audits can be valuable.
- Skill and experience of auditor/assessor dependent
- Should have validator participation (if required)
- Need to be interactive with opportunity for significant laboratory input

 Audits can too frequently show what you may want to see

...but what are we measuring?

- Establishing Data Quality Objectives (DQO)
 - Great in theory but all too infrequently used
 - Client or clients agent establish PARCS without consultation with the laboratory actually doing the work
 - Need to select laboratory and then establish PARCS
 - PARCS must be reasonable and attainable
 - Must be open to changes in Project Scope and even costs.

...but what are we measuring?

- Blind duplicates and spiked blinds are one of the best measures of lab's performance.
 - Prepare spikes in appropriate "matrix"
 - Only use analytes of true interest to the project
 - Cover all methods of interest
 - Gives "true" precision and accuracy estimates to compare with lab QA/QC finding
 - Realize that perfection is not a valid expectation
 - Adds costs and management expertise

...but what are we measuring?

- Data Validation should be an unnecessary expense
- Don't just adopt "Functional Guidelines"
- Insure validation is done by qualified professionals

Open a dialogue with the laboratory

So what is the Health of the commercial environmental testing industry?.....

Acceptable for the majority of the data but not necessarily from the majority of laboratories. There are numerous actions that both purchasers and providers of these services could/should be made to do to significantly improve our Health!

Depth

....how well the available technologies can detect all contaminants of concern at the required levels with adequate quality.

We are definitely swimming in the shallow end of the pool!

A little History....

We tend to think of ourselves as a rather mature industry but in fact (at least in this regard) we are far from it.

- This industry began with Water Pollution control.
- The tests or methods we used (and still use today) were screening tests at best.
 - BOD
 - COD
 - TOC – Solids
 - Phenols

A little History....

- As methods developed we continued in the private and public sectors of the testing business to develop screening tests; more sophisticated but screening nonetheless.
- While analyte specificity was added to some methods they, still tended to be used to screen for potential contaminants of concern.
 - TOX
 - RCRA Metals
 - HSL / TAL
 - 8260
 - 8270

Depth as technology to detect <u>all</u> contaminants.

- In combining all approved methodologies, estimate that we can analyze for <5 % of all the potential contaminants of possible concern to Human Health and the Environment.
- Primarily social and regulatory drivers.
- Very little emphasis is apparently given to increasing the depth of our science.

Depth as technology to detect <u>all</u> contaminants.

- Alkyl benzene-sulfonates and degradation products in soil
- Brominated flame retardants (tetrabromobisphenol A)
- Endocrine disruptors
- Estrogens
- Halonitromethanes
- Octyl- and nonylphenols and ethoxylates
- PFOA, PFOS
- Pharmaceutical compounds

Depth as technology to detect <u>all</u> contaminants.

- Personal care products
- Polychlorinated naphthalenes
- Organotins and other organo-metallics
- Steroids
- Antibiotics
- Hormones
- Disinfection Byproducts
- Degradation products

...at required levels with adequate cjuality.

- Sensitivity is a concern for all method constituents
- Have for years been estimating sensitivities inappropriately
- Too frequently sensitivity reflects what client requests as opposed to what a method can accurately provide
- Generally QA/QC results and ability to obtain DQOs are determined at inappropriate levels to provide meaningful insight at lower reporting levels

So what is the Depth of the commercial environmental testing industry?.....

To meet regulatory requirements, the Depth of the commercial testing industry is adequate.

To provide data which will assist in protection of human health and the environment, the Depth of our industry is shallow and there are few drivers to change this situation.

Breath

... how well the industry is able to measure all contaminants of concern in all matrices of concern.

Measurement by matrices

- Probably the industries greatest weakness
- Industry has grown primarily as a result of concerns in aqueous matrices
- Vast majority of approved methods support aqueous sample analyses
- Air, soil, solid and hazardous wastes, biota, tissues are problematic for many contaminants of concern.

So what is the Breath of the commercial environmental testing industry?.....

- Frankly, pretty narrow!
- Current literature does support activity in this area.
- Too frequently attempts are made to adapt existing approved aqueous methods to fit a new need.
- Need to apply Sound Science!

From the Commercial Laboratory Perspective, how can we enhance the Health, Depth and Breath of Environmental Monitoring in the US?

First, a few bits of reality...

We are a commodity!

- The industry remains in an over-capacity situation.
- Quality is assumed.
- Labs are caught in a cost spiral.
- Accreditations are insufficient differentiator.
- Cost is King
- Laboratory services are too infrequently included in the planning process.
- Method and technology development is virtually impossible in a commercial lab
- We are in a political environment which provides no regulatory drivers for change.
- Commonly thought of and/or treated as if fraudulent.
- Qualified chemists at a premium and very difficult to attract/retain.

...but hope is not lost!

Protection of Human Health and the Environment as well as Environmental decision making requires our data!

We have to get better at delivering it.

How Commercial Labs Compete

According to economists, business compete (will survive) based on three premises:

- Product Superiority
 - Labs virtually barred from competing at this level
 - Special products in our business revolve around innovation to processes not products
 - Enhancing data product & delivery our only option
- Customer Intimacy
- Operational Excellence

Proposed Actions for the Commercial Laboratory Community

- Require Laboratory Accreditation
- Develop, implement a mandatory requirement for Quality Systems in all labs
- Promote PBMS/Performance Approach
- Employ Sound Science over convenient policy
- Develop a partnership with EPA
 - Stress critical nature of what we do
 - Share common goals of serving the public

THE ENVIRONMENTAL MONITORING INDUSTRY: MUNICIPAL PERSPECTIVE

Jim Pletl, Chief, Technical Services Stacie Metzler, Quality Assurance Manager Paula Hogg, Chief, Laboratory HRSD Virginia Beach, VA

Overall Perspective

- Measurement systems and their objectives form the foundation for the environmental monitoring industry
- The federal government must ensure these systems are properly developed, tested and implemented nationally
 - Consistency
 - Legal equity
 - Environmental protection

 Only 40 CFR methods can be used to generate compliance data for regulatory uses

Overall Perspective

Municipal laboratories are permittees

Municipalities carry liability for:

- DMR Reporting
- Compliance decisions based on data
 - Citizen and public interest group lawsuits
- Enforcement body (Pretreatment)

Reliability of data is critical

Topics

Technology

Emerging Contaminants

Detection/Quantitation

Laboratory Accreditation

Discussion Points

Status/ Perspective

Barriers

Possible Solutions

Technology - Status

Analytical instrumentation, LIMS, analytical methods, sampling techniques

 Water quality goals continually moving towards lower concentrations/effects, requiring more sensitive yet reliable technologies

Technology - Status

 Advanced technologies exist, but should not be used to generate data for regulatory purposes without:

- proper validation, and
- consistency in implementation across all states

Environmental laboratories are struggling to meet the needs of the public and regulatory agencies

Technology - Barriers

- The method promulgation process does not keep pace with the needs of data users (and data providers)
 - Need for promulgated methods and technologies for constituents of interest at trace levels
 - New technologies are available with enhanced sensitivity but are not properly validated

 Inconsistent interpretation of methods between EPA regions, programs and among the states

Organics extraction techniques

Technology - Barriers

- Where is the line between "improvement" and "modification"?
 - Improvements to approved methods are not accepted though determinative steps remain the same

Alternative Testing Procedure (ATP)

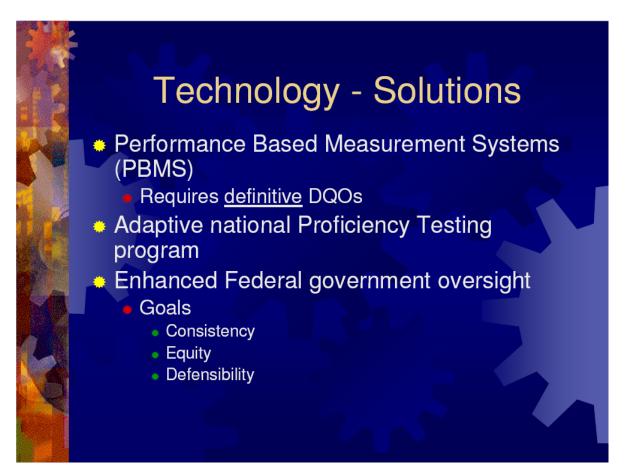

- Designed to address new technology
- Does not guarantee method promulgation
- Can lead to interstate inconsistencies

Technology - Solutions

 Promulgated system for timely method development, validation and approval
 Stakeholder involvement
 Identify issues
 Include feedback mechanism

Partnership between EPA and technology industry

 Facilitate and support technological advancements

Emerging Contaminants - Status

- Bleeding-edge technologies/approaches are suggesting environmental issues that the current regulatory paradigm can not adequately track
- Innovations in analytical and sampling technologies allow for detection of new compounds/effects
 - High resolution GC/MS and LCMS/MS
 - Single drop micro extraction
 - SPME (Solid phase micro extraction)
 - Endocrine disruptor bioassays

Emerging Contaminants - Barriers

Few promulgated methods

Reliability of reported data uncertain

- Key for decision management when continuously evolving methodologies are used
 - Changes in sensitivity
 - Quality control parameters
- DQOs are not consistently implemented for methods in use
- Interpretation of published data varies significantly

Emerging Contaminants - Solutions

- EPA must be more active in addressing public concerns from a scientifically sound perspective
- DQOs must be established before samples collected, measurements and interpretation
- Partnership between EPA and technology developers needed

Detection/Quantitation - Status

40 CFR Part 136 Appendix B – technical and policy issues

- Lack of MQO's
- Lack of verification
- Reporting relative to D/Q limits
- Matrix effects

 EPA formed FACDQ in 2005 to provide recommendations on how to address issues by 2008

Detection/Quantitation - Barriers

- Varied interpretation of current procedure
 - Instructions
 - Terminology
 - Results in inconsistent
 - detection/quantitation limit determinations

Inconsistent reporting policies Regulatory decisions

Detection/Quantitation - Barriers

Insufficient Data Quality Objectives
No standards for laboratory performance
Current procedure only has one MQO: 1% false positive rate for detection
MQOs for precision and bias are not included

Impact of changing procedures

- Procedural laboratory operations
- Reporting laboratories, permittees, States

Detection/Quantitation - Solutions

- Consensus on objectives for using D/Q limits
 - Stakeholders
- Procedure must meet consensus objectives:
 - MQOs
 - Continuing verification
 - Concise and clear
 - Applicable in multiple matrices

Detection/Quantitation - Solutions

Promulgate for all EPA programs

Guidance for consistent implementation

 Training and communication on new procedures and guidance from EPA

Lab Accreditation - Status

- National accreditation program nonexistent
- Accreditation/certification programs exist:
 - States (SDWA)
 - NELAC
 - Various program-specific inspections
- Inconsistency between programs
 - Multiple standards

Lab Accreditation - Barriers

- Lack of consensus across all stakeholders on many issues
- Waning federal support or oversight for national accreditation
- No infrastructure for support
- Program data quality objectives largely not available
- National PT program unavailable

Lab Accreditation - Solutions

- Federally funded and managed program
 Assemble stakeholder groups to achieve consensus
 - Standards
 - Programs
- Develop objectives for programs
- National PT program
- Avoid prescriptive standards

Health, Depth, & Breadth of the Environmental Monitoring Industry

Dr. Duane Boline Director, Div. of Health and Environmental Laboratories Kansas Dept. of Health and Environment

Health

Is the U.S. environmental testing industry delivering the quality of data needed?

Data Quality Objectives

 Data quality <u>requirements</u> are determined by the intended use of the data.

 Data quality <u>objectives</u> are normally established based upon the most restrictive potential use of the data vs. the intended use.

Technical Quality

- Accuracy
- Precision
- Representativness
- Comparability

Defensibility

- Does the analyst have the education and/or experience required to perform the test?
- Is the test method used approved by the accreditating authority for determination of the analyte?
- Was calibration performed within the required time period.

Defensibility (con't)

- Were all QC criteria required by the method achieved?
- Were sample preparation and analysis procedures completed within the required holding time?
- Are all actions related to analysis of the sample properly documented and traceable?

Ask the Customer

 "Delays in completion of environmental projects are often due to the need to assure the data (actually the information based upon the data) is correct."

 "In some cases the quality of testing could be less rigorous and still provide the information needed." (e.g. MDLs, method used, etc.)

Ask the Customer

"The issues involved in sampling provide more variability than the testing methods."

"Anticipate the project manager may not be familiar with testing methods and know there is a faster, cheaper method that will provide the information needed."

Health?

Is the U.S. environmental testing industry delivering the quality of data needed?

How is quality defined and by whom?

Health

 Quality has become a legal measurement vs. a technical measurement.

 The emphasis is focused on high quality analytical data obtained for samples of questionable validity.

Depth

Are the achievable detection limits adequate?

How are <u>required</u> limits of detection determined?

Customer Comment

 "A chemist can find almost anything almost anywhere."

 "The detection levels may provide information on concentrations far below that of any significant impact"

"But do we really know?"

Detection Limits

- Advances in technology have made lower detection limits achievable.
- The toxicity of a substance to a specific organism is unlikely to have changed significantly.
- Do we go lower because it is necessary to obtain information or because we can?

Depth

How well do the current technologies detect all of the contaminants of concern?

If a substance is not detected it does not become a contaminant of concern.

 As technology advances new concerns will be discovered.

Philosophical Consideration

"I became a chemist before chemicals became toxic!"

Breadth

How comprehensive is testing relative to the needs?

Protection and sustainability of our environment.

Protection of human health.

Philosophical Question

Do the needs drive advances in technology?

or

Do advances in technology expose needs of which we are unaware?

Ask the Client

"We need tests that will provide faster more accurate results for bacteria and viruses in our public water supplies. The results are variable and normally available after the fact."

Data Usability

A link between environmental data and public health data is needed.

 Epidemiological data (e.g. cancer clusters) compared to environmental data could be informative.

Biomonitoring

 Toxicity and required MDLs for test methods are primarily empirical.

Bio-monitoring is in its infancy!

 Environmental Health Tracking and Environmental Health Programs are needed.

Succession Planning

"We have trained our successors to think the same way we think."

"Our industry has developed tunnel vision."

"There is a need for a return to the scientific values of curiosity, creativity, and ingenuity to ensure identification and solutions for the new questions of the future."

Update on Activities Affecting the Industry

National Environmental Monitoring Conference

August 29, 2006

Jerry L. Parr

AGENDA

Part I: EPA Efforts

- Regulations
- Detection and
- Quantitation
- > Method updates
- > Other activities

Part II: Related Activities

- New and emerging analytes
- Laboratory accreditation
- DOD Quality System Manual

Regulations with New/Revised EPA Methods and Monitoring

- >2004 Water Methods Rule (Proposed)
- Stage 2 DBP Rule
- >UCMR 2 Rule (Proposed)
- LT2ESTWR Rule
- >Biological Methods Rule (Proposed)
- > Methods Innovation Rule

Water Methods Rule

- Proposed April 6, 2004
- New methods
- Updated versions of approved methods
- Revised method modification and analytical requirements
- Withdrawal of outdated methods
- Changes to sample collection, preservation, and holding time requirements

19 New Chemical Test Methods

- ASTM D6508, Dissolved Inorganic Anions by Capillary Ion Electrophoresis,
- QuikChem Method 10-204-00-1-X, Cyanide using MICRO DIST and flow injection analysis,
- Kelada-01, Automated Methods for Total Cyanide, Acid Dissociable Cyanide, and Thiocyanate,
- Method CP-86.07, Chlorinated Phenolics by In situ Acetylation and GC/MS,
- EPA 245.7, Mercury by Cold Vapor Atomic Fluorescence Spectrometry,
- SM 4500-Cl, Chlorine by Low Level Amperometry,
- ASTM D6888-03 Available Cyanide by Ligand Exchange-FIA,
- ASTM D 6919-03, Cations and Ammonium in by IC,
- > SM 4500-CI-D. Chloride by Potentiometry,

New Chemical Test Methods (Cont.)

- > ASTM D512-89 Chloride by Ion Selective Electrode,
- > SM 4500-CN-F, Cyanide by Ion Selective Electrode,
- > ASTM D2036-98 A, Cyanide by Ion Selective Electrode,
- > SM 4500-S2-G, Sulfide by Ion Selective Electrode,
- > ASTM D4658-92, Sulfide by Ion Selective Electrode,
- > SM 4500-NO3-D, Nitrate by Ion Selective Electrode,
- ASTM D99-003, Free Chlorine by Color Comparison Test Strip,
- Method OIA-1677, DW Available Cyanide by Ligand Exchange—FIA,

Radium-226 and 228 by Gamma Spectrometry, and

> EPA 327.0, Chlorine Dioxide by Colorimetry

New WET Test Procedure

Microtox 1010

Re-proposed Chemical Test Methods

First Proposed in 1994

- > 200.2, Total Recoverable Elements Digestion
- > 200.8, Metals by ICPMS
- > 200.9, Metals by Stabilized Temperature GFAA

> 218.6, Hexavalent Chromium by IC

- > 300.0, Inorganic Anions by IC
- Method 353.2, Nitrate and Nitrite by Colorimetry

Revisions to 180.1, 200.7, 245.1, 335.4, 350.1, 351.2, 353.2, 365.1, 375.2, 410.4, and 420.4.

Equivalent ASTM and SM methods also proposed

Updated Versions of Current Methods

- An errata sheet for the WET manuals
- 70 ASTM methods
- 85 Standard Methods

Methods published in the 16th edition of Official Methods of Analysis of AOAC International, 1995

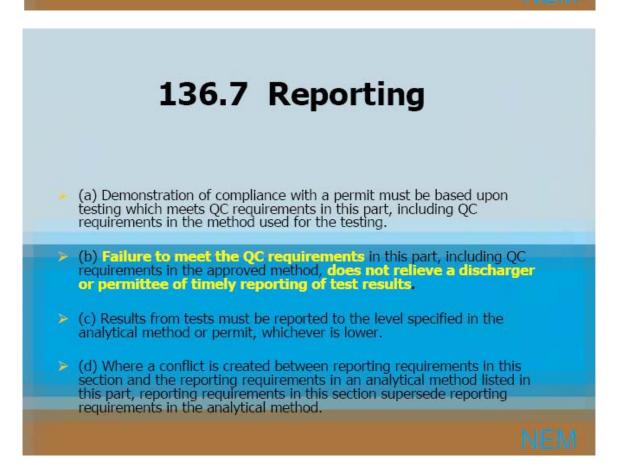

Method Modifications

- Replace the mercury catalyst in TKN methods
- Approve the use of styrene divinylbenzene beads and Hach StablCal as alternatives to the formazin standard for Turbidity

Allow the use of capillary GC columns for Methods 601-613, 624, 625, and 1624B

Revised Method Requirements

- Clarify that analysts need only meet method performance requirements for target analytes
- Allow method modifications without prior EPA approval by passing QC checks
- QC failure does not allow reporting of results
- Clarify that results be reported to the level specified in the method or required in the permit, whichever is lower.

Withdrawal of Methods

- Delete Methods 612 and 625 for dichlorobenzenes
- Withdraw approval for all oil and grease methods that use Freon-113
- Withdraw Syngenta Method AG-625 for monitoring atrazine

Side Note Regarding Freon

 Essential Laboratory Use Rule (2/11/02 Federal Register)

Three-year exemption for the use of Freon in environmental test methods, until 12/31/05

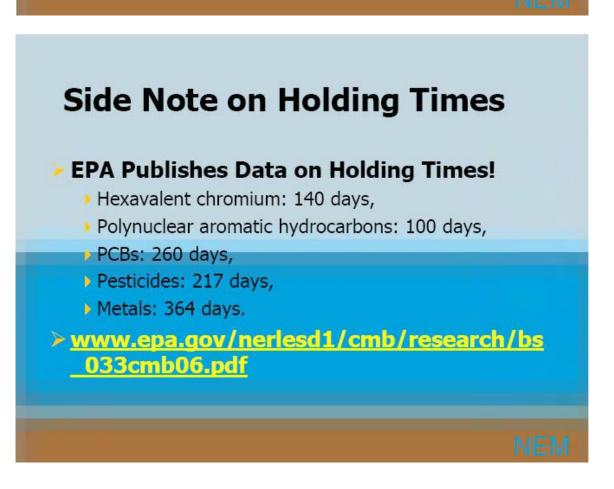

- Rule does not apply to laboratories!
- EPA planning to remove 413.1 from Part 136; 413.2 and 418.1 were never promulgated

EPA Clarification Memo, 12/30/05

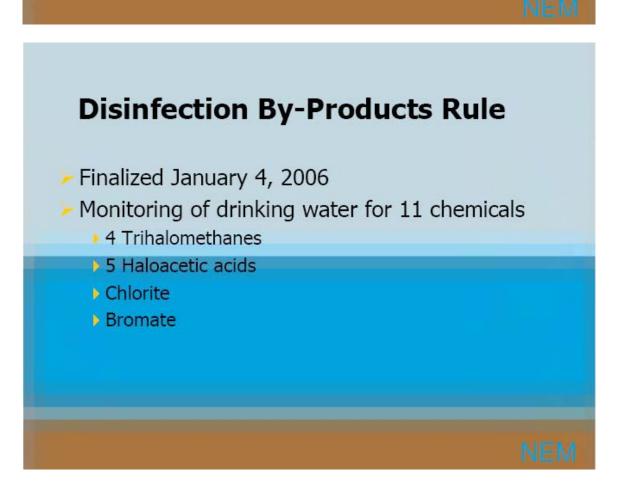

Sampling and Preservation

- Change 4 C to 0-6 C
- Change HT for Cr⁺⁶ to 28 days
- Various changes for mercury
- > No acid preservation for metals in the field
- > HT starts at end of composite period
- > Other minor changes
- Probable typographical errors

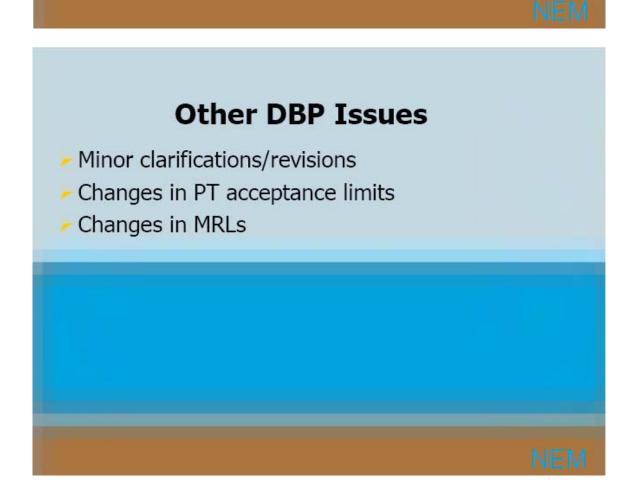

Current Status of this Proposal

- Comment period closed in June, 2004
- Hundreds of comments received
- Microtox method appeared to have the most negative comments
- Method flexibility second, for and against
- EPA indicates final rule this fall (but 1994 proposal was supposed to be done in 1995)

DBP Methods

- Approved 15 Standard Methods
- Approve three ASTM methods
- Approve EPA Methods:
 - 327.0 Revision 1.1
 - 552.3
 - 317.0 Revision 2
 - 326.0
 321.8
 - + 415.3 Revision 1.1
- > Update the citation for Method 300.1
- Standardize the HAA5 sample holding times and the bromate sample preservation procedure and holding time.

Unregulated Contaminant Monitoring Rule: Phase 2

Proposed August 22, 2005
 Monitoring of drinking water for 26 chemicals using 9 methods

Monitoring to occur 2007-2011

NEM

UCMR 2 Analytes

List 1. Assessment Monitoring

- 1,3-dinitrobenzene
- 2,2',4,4'-tetrabromodiphenyl ether
- 2,2',4,4',5-pentabromodiphenyl ether
- 2,2',4,4',5,5'-hexabromobiphenyl
- 2,2',4,4',5,5'-hexabromodiphenyl ether
- 2,2',4,4',6-pentabromodiphenyl ether
- > 2,4,6-trinitrotoluene
- Dimethoate
- Hexahydro-1,3,5-trinitro-1,3,5triazine (RDX)
- Terbufos sulfone
- > Perchlorate

List 2. Screening Survey

- Acetochlor
- Acetochlor ESA
- Acetochlor OA
- Alachlor
- Alachlor ESA
- > Alachlor OA
- > Metolachlor
- Metolachlor ESA
- Metolachlor OA
- > N-nitroso-diethylamine
- N-nitroso-dimethylamine
- N-nitroso-di-n-butylamine
- N-nitroso-di-n-propylamine
- N-nitroso-methylethylamine
- N-nitroso-pyrrolidine

Proposed Methods

- > 314.0 enhanced (IC/Conductivity)
- > 314.1 (IC/Conductivity)
- > 331.0 (LC/MS or LC/MS/MS)
- > 332.0 (IC/MS or IC/MS/MS)
- > 527 (SPE/GC/MS)
- > 521 (SPE/GC/CI/MS/MS)
- > 535 (SPE/HPLC/MS/MS)
- > 525.2 (SPE/GC/MS)

Other Aspects of UCMR 2

Lowest Concentration Minimum Reporting Limit (LCMRL) proposed

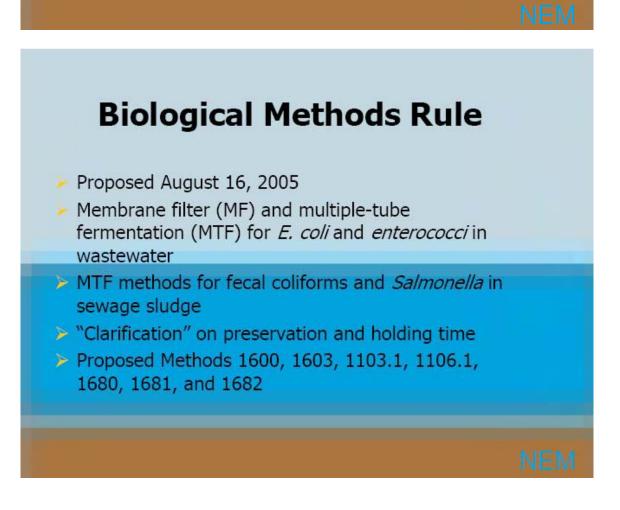

Participating laboratories must be

approved by EPA

Expected to be final Fall, 2006

Long-Term 2 Enhanced Surface Water Treatment Rule

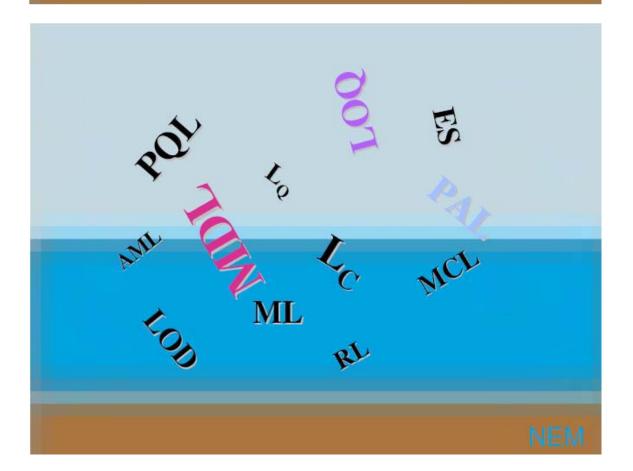

- > Finalized January 6, 2006
- Monitoring of source water used for drinking water for Cryptosporidium, E. coli, and turbidity
- Labs must be approved by EPA for Cryptosporidium monitoring
- Promulgated Methods 1622 and 1623 for Cryptosporidium
- > Established holding time of 30 hours for *E. Coli*

Methods Innovation Rule

June 14, 2005

- Applies to SW-846 methods
 - Clarifies difference between methods that are required and those that are intended as guidance
 - Finalizes revisions to Update IIIB
 - Removes required uses of Chapter Nine
 - > Withdraws cyanide and sulfide reactivity guidance

Lloyd Currie's Fundamental Work

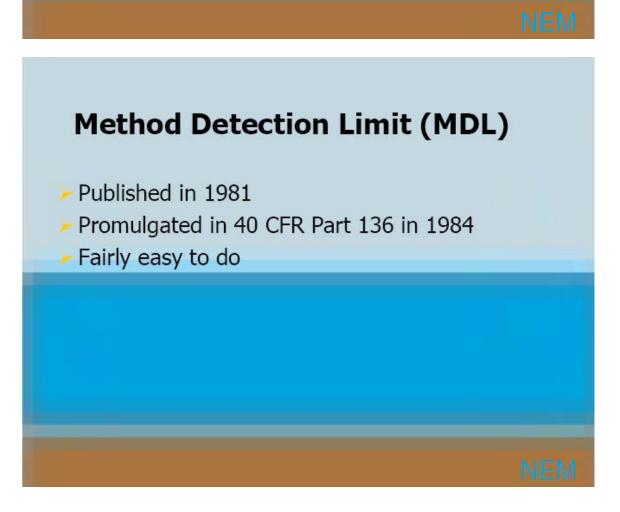

Analytical Chemistry, 1968

Critical Level (L_C)
Result indicates detection

Detection Limit (L_D)
Procedure may be relied upon to lead to detection

Determination Level (L_Q)
Procedure sufficiently precise to yield quantitative result

Procedure: Standard deviation (s) from blank measurements (i.e., precision-only)

Assumptions in the MDL

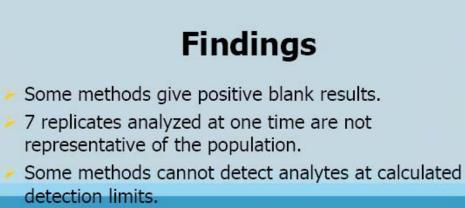

Sample standard deviation (7 replicates) represents the population standard deviation

Blank results are centered around zero

Qualitative identification is possible

> Sample recoveries are centered around 100%

For some methods, low recoveries were observed at low concentrations.

The assumptions use to establish the MDL procedure are not valid!

A New Approach

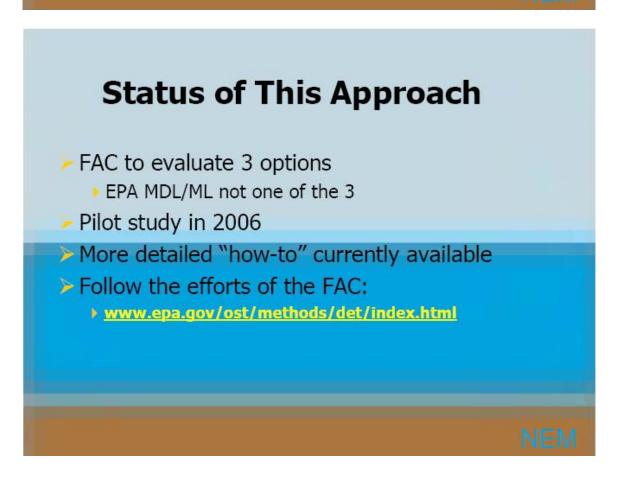

Developed by work group representing broad crosssection of commercial, governmental and scientific organizations (e.g., ASTM, ACIL, Alliance of Automobile Manufacturers, and AWWA).

Based on definitions of L_O, L_D and L_C

Consensus Principles

- Procedures must take into account the variability and bias of method blanks
- The definition of quantitation must include both precision and bias
- False positives and false negatives must be addressed
- Precision, bias and qualitative identification must be addressed
- Must include procedures for ongoing demonstration of sensitivity

Lowest Concentration Method Reporting Level (LCMRL)

- Lowest true concentration for which future recovery is predicted with high confidence (99%) to be between 50 and 150% recovery
- Determined during method development
- Implementing laboratory has to verify that level can be achieved
- Rigorous, complex approach for developer; fairly simple for implementing lab
- Proposed as part of UCMR 2
- > See Environ. Sci. Technol., 40 (1), 281, 2006

SPE DETECTION OF CONTAMINANTS IN PUBLIC WATER

Hall, Thomas; Horizon Technology, Inc.

With the growing threat of hazardous chemical agents possibly being introduced into public water supplies and in-coming process water, there is a greater need for monitoring and detection of trace quantities of chemical contaminants. Recent advancements in Solid Phase Extraction (SPE) adsorbent chemistries and new technologies for drying and concentrating samples for GC and GC/MS analysis, allow many water samples to be analyzed quickly and accurately to determine if there are any chemical agents present.

Solid phase extraction (SPE) is based on the principals of classical chromatography. XAD resins were used as early as 1972 to isolate drugs from biological fluids. Since that time, numerous adsorbents for size exclusion, normal and reverse phase, and ion exchange SPE have been developed. Originally configured as a cartridge, SPE disks were introduced in the late 1980s and have been incorporated into many extraction methods. Recently, new adsorbents have been introduced that show improved performance for a wide range of analytes including acid, base and neutral compounds. These adsorbents feature divinyl benzene polymers that have been modified to improve interactions with aqueous sample matrices and provide a mixed mode for solute retention.

In addition to improved chemistries, SPE equipment has also advanced. Automated systems are now available for the extraction, water removal, and concentration steps that are normally required prior to GC-MS analysis. Hydrophobic membranes are now available to remove trace water from the organic extract. In contract to the traditional drying method employing Na2SO4, these membranes permit the drying process to be automated. Concentrators have been commercially available for years; however, because the drying step had to be performed manually they could not be integrated with automated evaporators/concentrators. Today the entire process can be automated from start to finish.

This presentation will demonstrate the effectiveness of automated SPE techniques for extracting a wide range of chemical classes and functionalities to meet these emerging needs. Using EPA Method 3535A as a starting point, extraction methods and techniques will be discussed and recovery data will be reviewed for acid, base, and neutral compounds of interest.

Fast Automated SPE for the Detection and Analysis of a wide spectrum of Chemical Contaminants in Public Water Supplies and Process Waters

Tom Hall Horizon Technology www.horizontechinc.com

Agenda

- Overview of Solid Phase Extraction SPE (Using Disks)
- Benefits of SPE vs. Liquid-Liquid Extraction (LLE)
- Discuss EPA Methods for SPE
- Benefits of Automation of SPE
- Optimizing the Extraction
- Drying and Concentration
- Recovery Data
- Summary

What is SPE?

Solid Phase Extraction is an extraction process whereby an aqueous sample is filtered through a bed of sorbent particles, the analytes of interest are removed from the aqueous sample, and concentrated onto the sorbent. Once concentrated, the analytes are removed from the sorbent by a series of eluting solvent rinses.

Comparison of LLE vs. SPE Disk Methods

<u>LLE</u>

Uses 200 - 500 ml solvent

Shaking / Continuous process

Forms emulsions / surfactants

Little Selectivity

Requires solvent removal

Takes 2 hours / sample

<u>SPE Disk</u>

Uses 20 - 30 ml solvent

Filtration process

No emulsions formed

Wide Selectivity (adsorbent)

Optional

Takes 20 min / sample

What are the Advantages of SPE?

- SPE Uses Less Solvent than a Typical LLE Procedure
- SPE is Faster; only 20-30 min for a 1-liter sample
- SPE costs considerably less than LLE
- SPE Provides comparable / better recoveries than LLE
- EPA Methods are constantly being developed for SPE

Current EPA Methods for SPE

- Drinking Water
- Waste Water
- Oil and Grease
- **SW-846**
- Metals

(500 Series)

(600 Series)

(1664A)

(3535A--8000 Series Prep)

5

6

(Evolving)

The Procedure for Using SPE Disks

- Pre-wash the disk with the final eluting solvent.
- Pre-wet the disk with solvent compatible
- Filter the water sample through disk.
- Elute / Extract the disk with solvent.
- Dry, concentrate, and analyze the extract.

Why Automate SPE ?

- Increases productivity by improving sample throughput
- Improves accuracy and precision by eliminating variations due to human operators
- Reduces laboratory costs by reducing operator time, glassware, and solvent usage
- Reduces worker exposure to solvents
- Consistent control over critical air dry steps

SPE-DEX[®] 4790 Extractor

- Fully Automated, Modular Design
- Run up to 8 Extractors
- Run independently
- Run individual methods
- Use 47, 50, and 90-mm SPE disks
- Designed for all SPE Chemistries
- Preprogrammed EPA methods
- Bench top operation
- High Sample Throughput

Automated Extractor System % Recovery of 525 analytes in Lab Fortified Blanks target conc = 2.0 ug/L

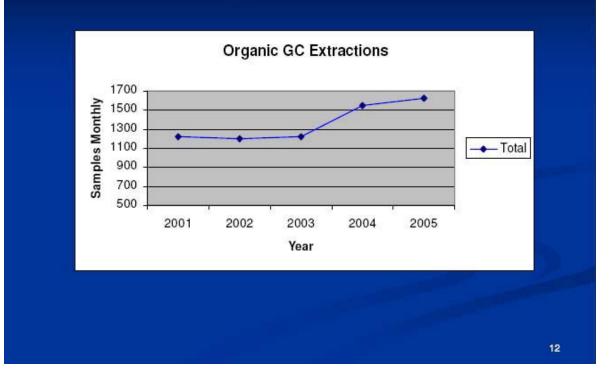

Target Compounds	1	2	3	4	<u>5</u>	Average Std	Dev
Hexachlorocyclopenta	94	98	95	95	96	96	1.4

Benzo(a) pyrene	99	98	98	98	97	98	0.6

Measuring Throughput

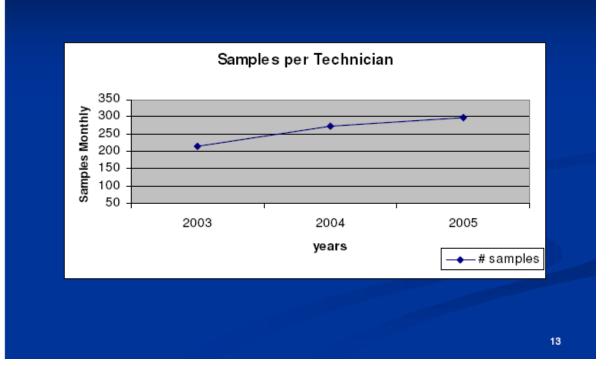

Measurements include:

- Number of Samples extracted
- Samples / FTE
- Overtime / Labor Cost Reduction
- Turn Around Time Reduction

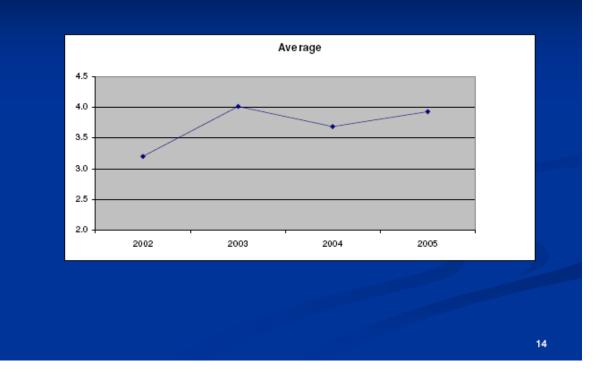

Sample Workload

Reduced Labor Cost

Traditional Concentration Steps

- Drying done with Sodium Sulfate
- Water bath
- Glassware
 - KD flask, Concentrator, Snyder Column
- Nitrogen Concentration
 - N-evap

How to Solve the Drying Problem?

- Horizon developed the DryDisk [™] Separation Membrane.
- The DryDisk[™] is a PTFE membrane, of the proper pore size and thickness, whereby the solvent can pass through, while retaining the residual water.
- The DryDisk[™] has been optimally designed to use vacuum to increase the drying process.
 - Typical flow rates are 100 ml / min
- Retained residual water can be re-extracted; improved recoveries.
- DryDisk[™] is available in 2 sizes:
 - 65 mm diameter disk
 - 20cc syringe barrel

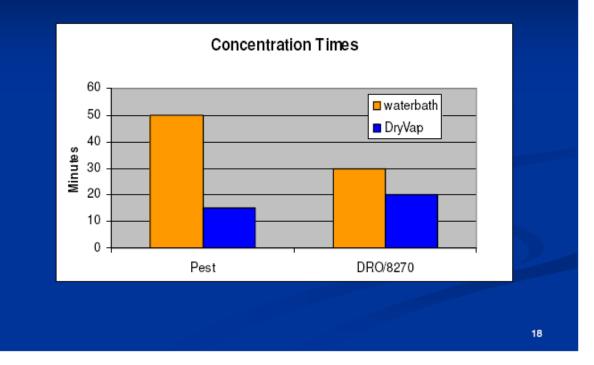

DryVap[™] Concentration system

- Automatic In-Line Solvent Drying
- Selectable Solvent Dry Times
- Internal Heating Elements
- Automatic Heater Shutoff
- Utilizes Vac, Gas, and Heat
- Innovative Gas Sparging System
- Individually Sealed Vessels
- Reliable End Point Detection
- Bench Top Operation
- Combines KD and Nitrogen blow down into a single system

Water Bath vs. Dry Vap

Summary

- EPA Method 525.2 is currently the SPE method of choice for rapid screening Chemical Contaminants in Water Sources
- Automating this method will greatly increase sample throughput in the time of a threat.
- Automating the Drying and Concentration greatly increases throughput in addition to extraction automation
- Rextraction rate is dramatically reduced

ENDOCRINE DISRUPTING COMPOUNDS IN RIVER WATER

Borton, Christopher; Applied Biosystems Ellis, Robert; MDS Sciex Ghobarah, Hesham; Applied Biosystems Jones, Elliott; Applied Biosystems Olson, Loren; Applied Biosystems Schreiber, Andre; MDS Sciex

Endocrine disrupting compounds (EDCs) are a wide range contaminates ranging from pesticides, herbicides, pharmaceuticals, personal care products (PPCP), and steroids that are thought to disrupt the endocrine function of mammals and fishes. Recently the biological effects of EDCs have been at the forefront of concern. In order to properly assess the effects of these compounds on our environment it is necessary to accurately monitor the presence in their environment. Presented is a method for analyzing up to 100 EDC compounds using LC/MS/MS. This method presents a straight forward approach for the analysis of these compounds with excellent sensitivity and ruggedness.

The method uses an API 4000[™] LC/MS/MS system equipped with a Shimadzu Prominence autosampler and binary LC pump. Ionization is achieved by using electrospray ionization (ESI) and Atmospheric Chemical Ionization (APCI) in the DuoSpray source. All compounds are monitored using two multiple reaction monitoring (MRM) transitions per compound. The most sensitive MRM is used for quantitation while the second MRM is used for qualitative confirmation using ion ratio determinations. Ionization in negative and positive polarity is necessary to detect compounds of various chemical properties. Chromatography is performed on a C18 reverse phase column. A water/actetonitrile gradient with 0.01% formic acid is used for separation. Sample preparation is performed using solid phase extraction.

Up to 100 endocrine disrupting compounds have been analyzed using this methodology. Detection and quantitation of all compounds is achieved down to low part per trillion levels.

<u>Christopher Borton</u>, Loren Olson, Hesham Ghobarah, Elliott B Jones, and Andre Schreiber LCMS Applications Group Applied Biosystems/MDS Sciex

LC/MS/MS Approach to Endocrine Disruptors and PPCP

Outline

2

- Introduction
 - What are endocrine distruptors (EDC)
 - Method development strategies and hardware
- 75 EDCs using QqQ scans on a 4000 Q TRAP[®] System
 - Single injection with polarity switching
 - Simultaneous quantitation and confirmation
- 25 EDCs using hybrid scans on a 4000 Q TRAP[®] System
 - Multiple injection with dedicated ionization modes (DuoSprayTM Source)
 - High throughput quantitation and spectral confirmation
 - Hybrid scan mode approach

Introduction – Why Study Endocrine Disruptors?

- Endocrine disruptors affect health of humans and aquatic ecosystems
- Pesticides, industrial waste, pharmaceuticals, and personal care products
 Many act as hormone mimics
- Endogenous hormones potent effects on development
 - Thus, ECDs can also have adverse effects, even at seemingly low levels
- Criteria for testing not set or are outdated
- Transgenerational effects / bioaccumulation
- Population growth
- New tools and techniques are needed
 - Identify threats to the environment
 - Take action before adverse health effects are seen in organisms

3

LC/MS/MS Approach to Endocrine Disruptors and PPCP

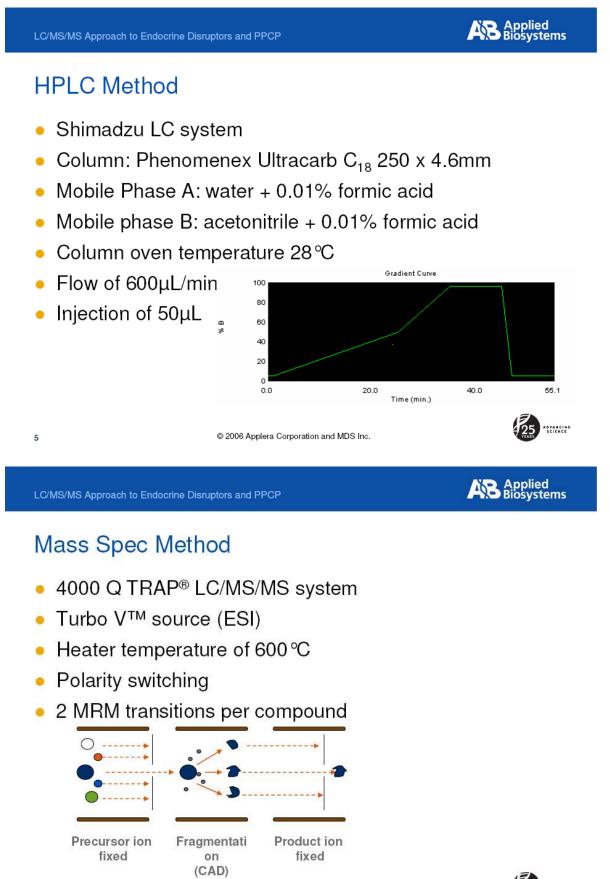

Strategies for LC/MS/MS Method Development

- Demonstrate feasibility of using different strategies LC/MS/MS for EDCs.
 - Screen, quantitate and confirm in environmental water samples.
 - ESI vs. APCI or DuoSpray[™] Source
 - Polarity switching
 - Single vs. multiple injections
 - Performance and practicality
- Evaluate sample preparation
 - SPE
 - Direct detection no derivatization
- Hardware and software automation
 - Increase efficiency data thoughput
 - Less manual review of data
- Data Reduction
 - Analyst[®] 1.4.1 and accessory software
 - Draw conclusions quickly and with confidence

Applied Biosystems

4000 Q TRAP[®] Method for Optimized Quantitative Performance and Qualitative ID in Treated Tap Water

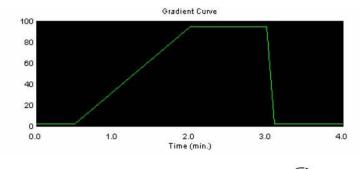

- Not sample limited
 - Multiple injections possible
 - Higher throughput chromatography
- Sensitivity, robustness, linearity, precision are a priority
 - DuoSpray[™] Source
 - Dedicated polarity
- Smaller, more focused analyte list (25 total)
- Spectral confirmation and the ability to do qualitative ID on unknowns
 - MRM IDA (Information Dependant Acquisition)

HALOACETIC ACIDS BY ION CHROMATOGRAPHY

Antonsen, Stephen; Dionex Corporation Aribi, Houssain El; MDS Sciex Sakuma, Takeo; MDS Sciex

Disinfection of drinking water by chlorination can lead to generation of carcinogenic species, such as haloacetic acids (HAA).

Chlorination has been linked epidemiologically to bladder, kidney and rectal cancers. Brominated acids are linked to nephrotoxic, neurotoxic and hepatotoxic effects, and Chlorinated acids have been shown to induce tumours.

Analysis of HAA in chlorinated drinking water is described in EPA method method 552.1. Monitored species are monochloroacetic acid, monobromoacetic acid, dichloroactic acid, dibromoacetic acid, trichloroacetic acid, tribromoacetic acid, chlorodibromoacetic acid, dichlorobromoacetic acid and chlorobromoacetic acid. Method 552.1 required acidification to pH5 with Sulfuric acid followed by a 2 hour hot-methanol derivatization and analysis by GC-ECD. Detection limits are in the fractional ppb range.

Ion chromatography (IC) linked to triple quadrupole mass spectrometry (MS/MS) offers significant advantages to the testing laboratory: no derivatization, lower detection limits (low ppt) and greater specificity.

In this work, an ion chromatography method was developed and interfaced to a triple quadrupole mass spectrometer. The requirements and considerations in linking IC to MS/MS will be demonstrated and the use of the method will be illustrated using natural and spiked chlorinated drinking water matrices.

Analysis of Haloacetic Acids and Bromate by IC-ESI-MS/MS

Houssain El Aribi, Ph. D.

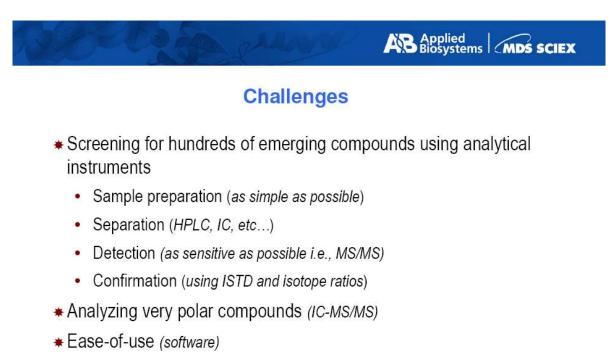

AB Applied Biosystems CIEX

LC- or IC- MS/MS Topics in Environmental Analysis

- * Pesticides (target analysis, screening, very polar pesticides)
- * Perchlorate
- * Disinfection by-products: haloacetic acids, bromate, trihamethanes, etc...
- * Estrogens and endocrine disruptors
- * Fluorinated compounds
- * Brominated flame retardants
- * Polycyclic aromatic hydrocarbons
- Explosives
- * Algal toxins and shellfish toxins
- Biogenic amines
- Antibiotics

They are found in contaminated water, food, beverages, soils, etc... They could pose a serious threat to human health.

* Screening for emerging compounds, etc....

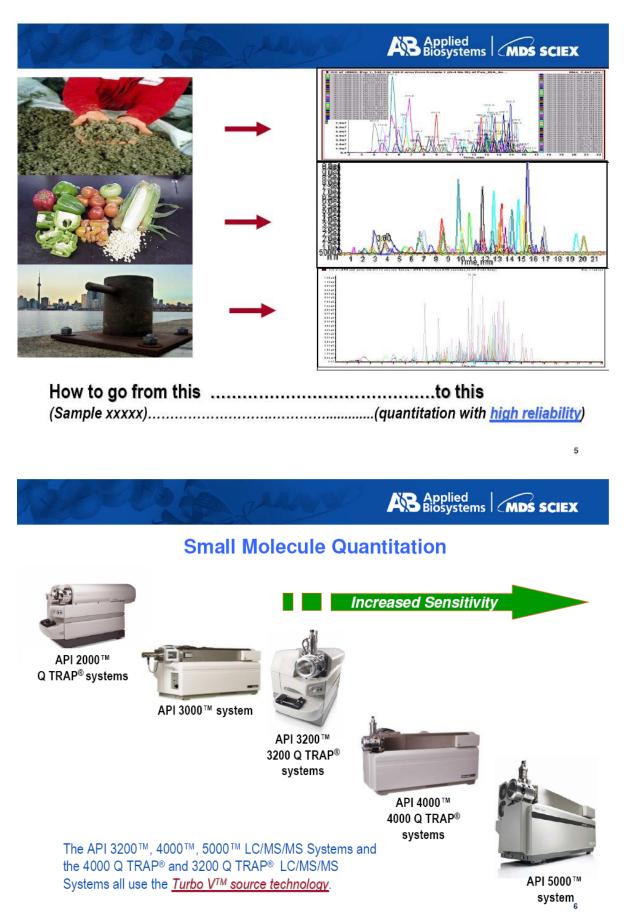

3

AB Applied Biosystems MDS SCIEX

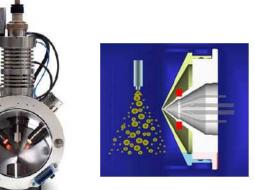

LC- or IC-MS/MS Involves...

- Chromatography separation of analytes
 - Pumps
 - Autosampler
 - Column
- Ionization ion production
 - Electrospray (ESI, TurbolonSpray[®] source)
 - Atmospheric Pressure Chemical Ionization (APCI)
 - Atmospheric Pressure Photo Ionization (APPI)
- MS filtering ion transmission
 - Q1 Selected Ion Monitoring (SIM)
 - Q1-Q3 parent to product ion transitions (MRM); highly specific
 - Other possibilities as well...
- Detection ion detection (signal to peak)
- * Data analysis
 - Qualitative (what is it?)
 - Quantitative (how much is present?)

4

- > Rugged, Reliable, Easily Interchangeable
- > Orthogonal Sprayer: Enhance sensitivity and minimize contamination
- > Covers a wide range of applications and compounds
- > Accommodates diverse range of flow rates up to 3 mL/min
- > Quick change between ESI and APCI probes

Analysis of haloacetic acids and bromate using API 3200™

Applied Biosystems MDS SCIEX

Haloacetic Acids (HAAs) and Bromate in Water

Chloronated HAAs: MCAA, DCAA and TCAA are usually formed during the disinfection of water with chlorine or chloramine^[1-4].

Brominated HAAs: MBAA, DBAA, TBAA are formed during disinfection when the source water also contains bromide ions^[1-4].

The presence of bromide ions and MCAA may also lead to mixed CBAA^[5,6].

Human consumption of chlorinated drinking water has been epidemiologically linked to bladder, kidney, and rectal cancers^[7,8].

DCAA and TCAA are animal carcinogens^[9,10].

Bromate (BrO₃⁻) is also a disinfection by-product formed during ozonation of drinking water supplies containing bromide ions^[11] and has been judged as a potential carcinogen.

Analytical Methods for HAAs and Bromate in Water

- The analytical methods required for compliance monitoring of the HAAs are the US EPA methods 552 series, which involve GC-ECD analysis [12-15]. These methods require acidification to pH 0.5 with sulfuric acid, a liquid/liquid extraction, and a two-hour hot methanol derivatization.
- # HPLC and CE have been also used for the determination of HAAs, however, the detection limits were unsatisfactory, and recoveries of some analytes were poor^[16-18].
- The US EPA methods for the analysis of bromate are the <u>300 series</u> using either ion chromatography (IC) with conductivity^[19-22] or IC with ion coupled plasma (ICP)/MS^[23].

EPA Regulations

- MCAA, DCAA, TCAA, MBAA, and DBAA are cited in the US EPA HAA5 regulation. These five HAAs do not exceed a MCL of <u>60 µg/L</u> in drinking water.
- * EPA has also established a rule to regulate bromate at an average of <u>10 µg/L</u> in drinking water.

Because of the high toxic and carcinogenic risks of some of the HAAs, reliable and fast analytical methods without derivatization are needed to monitor their presence in water.

Direct determination of HAAs and bromate by suppressed ion chromatography (IC) with hydroxide eluents coupled with electrospray (ESI) and tandem mass spectrometry (MS/MS) is an alternative and desirable solution.

Analysis of haloacetic acids and bromate using API 3200™

Applied Biosystems MDS SCIEX

Results for Treated and Untreated Water Samples

25

AB Applied Biosystems MDS SCIEX

Conclusion

- The IC-ESI-MS/MS method was found to be a robust, specific and sensitive system for the determination of HHAs and Bromate.
- A very significant advantage over GC methods is that no sample pretreatment or derivatisation is required.
- Dionex and Applied Biosystems/MDS Sciex are providing a sensitive validated package for the analysis of polar compounds.

Thank you for listening

ADVANCES IN PREPARATION AND ANALYSIS OF ORGANIC COMPOUNDS: IMMOBILIZED LIQUID EXTRACTION OF DRINKING OR WASTE WATER AS A NEW SAMPLE PREPARATION TECHNIQUE FOR GC/LC ANALYSIS

Gullett, Robert; Wohleb, Ian; Wohleb, Robert, and Wohleb, Thomas – Wohleb Scientific, Inc.

Classical methods for the extraction of water samples employed in EPA and Standard Methods for the analysis of drinking water or waste water are based on either liquid/liquid extraction or liquid/solid extraction employing solid phase extraction disks (SPE) disks. Liquid/liquid extraction is the less desirable of the two because it involves considerable time, labor, and expense. SPE disks reduce solvent consumption but still require sample concentration and are impractical to use when large quantities of particulates are present.

In this study we investigated the use of Immobilized Liquid Extraction (ILE) for aqueous environmental samples. ILE is a simplified procedure for extracting organic compounds from aqueous matrices (drinking water, groundwater, wastewater and etc.). ILE is a form of liquid/liquid extraction in which the "organic" phase is immobilized on the surface of an ILE device.

We chose ILE caps for this study. A portion of each ILE Cap was coated with a thin layer of a non-extractable homogeneous sorptive polymer. We evaluated the most commonly used hydrophobic elastomer polydimethylsiloxane (PDMS) and compared it to the more selective fluoro, phenyl and cyano siloxanes. The coating acts as the extraction medium, into which a targeted compound, or analyte(s), partition(s) from the sample.

For each extraction we placed an ILE cap on a bottle or vial that contained an aqueous sample. The vessel was agitated by a mechanical wrist-shaker such that the cap came in repeated contact with the aqueous sample. Upon completion of the extraction, the analyte-laden cap was removed and placed on a vial containing a small amount of suitable solvent (100-300 μ L). The analytes were "back-extracted" into the solvent. The resultant extract was then ready for analysis by gas or liquid chromatography.

In this study we evaluated extraction efficiency and detection limits for pesticides, TPH, PCBs and semivolatiles. We present data on the effect of complex matrix interferants and evaluate increased throughput, decreased costs, greater precision, and reduced solvent usage and subsequent disposal.

Immobilized Liquid Extraction of Drinking or Waste Water as a New Sample Preparation Technique for GC/LC Analysis

Robert H. Wohleb, Ian J. Wohleb, Thomas J. Wohleb, Robert N. Gullett Wohleb Scientific, Inc., Ferndale, CA USA

ABSTRACT

Traditionally, techniques used for the extraction of organic compounds from drinking and waste water samples employed in EPA and Standard Methods are based either on liquid/liquid extraction or liquid/solid extraction employing solid phase extraction (SPE) disks or cartridges. Liquid/liquid extraction is the less desirable of the two because it involves considerable time, labor, and expense. SPE reduces solvent consumption, but still requires sample concentration, and is impractical when large quantities of particulates are present in a sample.

This study investigates Immobilized Liquid Extraction (ILE) as an alternative technique for preparing aqueous environmental samples for analysis by gas or liquid chromatography. ILE is a form of liquid/liquid extraction in which the "organic" phase is immobilized on the surface of an ILE device. Though the ILE method may be applied to a number of procedures involving the extraction of organic compounds from aqueous matrices (drinking water, blood serum, wastewater, etc.), the scope of this study is strictly environmental, specifically relating to EPA methods 508, 525, 8270 and 8082. The effectiveness of the ILE method was evaluated in the extraction and subsequent analysis of polychlorinated biphenyls (PCBs) and other semivolatiles from spiked water samples. Method detection limits, reduced sample sizes and solvent usage, complex matrix effects, and enhanceable selectivity are discussed.

INTRODUCTION

To best evaluate the viability of ILE as a potentially effective EPA method for preparing aqueous environmental samples, we performed a series of experiments to determine method detection limits, extraction efficiency and data precision.

ILE shares many of its fundamental principles with liquid/liquid extraction (LLE), solid phase micro extraction (SPME), and stir bar sorbtive extraction (SBSE). The extraction is performed by an equilibrium process that depends on the analyte's partition ratio between the aqueous phase and the immobilized organic phase ($K_{PDMS/W}$), and on the phase ratio (β). As the ratio of the volume of organic phase relative to the volume of the sample (i.e., the phase ratio) increases, extraction efficiency increases. The partition ratio is analyte-specific, and defined as the concentration of an analyte in the PDMS relative the concentration of the same analyte in an equilibrated sample (note: the partition ratio of PDMS/Water is approximately equal to the partition ratio for octanol/water). From only this information one can estimate the expected efficiency of the extraction of any compound.

As stated earlier, the "organic," or extracting, phase is immobilized on the surface of an ILE device. This surface may be the inside of an autosampler vial, the inside surface of a bottle or vial cap, the inside surface of a disposable pipette or tip, or a number of other possibilities.

ILE Caps were chosen for this study. The septum of each ILE Cap is coated with a thin layer of a non-extractable homogeneous sorptive polymer. In this case, the most commonly used hydrophobic elastomer, polydimethylsiloxane (PDMS), was used, although selectivity may be altered or enhanced by using fluoro, phenyl or cyano siloxanes.

The polymer coating acts as the extraction medium, into which a targeted compound, or analyte(s), partition(s) from the sample matrix. Optionally a co-solvent may be used to enhance extraction speed and selectivity. The analyte(s) are then back-extracted from the polymer into a small amount of suitable solvent, and the resultant extract is ready for analysis by gas or liquid chromatography (in this experiment, all extracts were analyzed by a GCMS).

MATERIALS & METHODS

Instrumentation

Extracts were generated using the Wohleb Scientific, Inc. 24mm Immobilized Liquid Extraction (ILE) Cap. Each ILE cap septum is coated with a 508 micron thick layer of polydimethylsiloxane, resulting in a 122 uL "organic" phase. The appropriate volume of organic phase is determined by sample size, and caps with different volumes of polymer may be available to ensure the best results for samples of a variety of sizes.

Analysis of the extracts was performed by a Hewlett Packard 5971 GC-MS with a splitless injection port in scan mode and a 30 m x 0.25 mm i.d. x 0.25 μ m VB-5 column. All samples were injected manually, which may be a source of additional uncertainty in recovered data.

Method

For each extraction, an ILE cap was placed on a 250 mL bottle containing a 100 mL water sample that was spiked with known quantities of one or more analytes. All internal standards and analytes of interest were present in each sample at concentrations of $0.5 \ \mu g/L$ (other than pentachlorophenol, which was at a concentration of $2.0 \ \mu g/L$). A 100 μ L aliquot of methylene chloride was added to each sample to add selectivity to and enhance the partitioning of analytes from the sample into the polymer (this co-solvent extraction step is described and evaluated in greater detail in the discussion section). The sample-containing vessel was then agitated by a mechanical wrist-shaker for 1 hour in a manner such that the cap came in repeated contact with the sample. This agitation disrupts the sample-polymer interface, thereby accelerating partitioning from the sample into the PDMS.

Upon completion of the extraction, the analyte-laden cap was removed and placed on a 10 mL conical bottom vial containing 100 μ L of acetone. The vessel was then agitated for 30 minutes to accelerate partitioning from the methylene chloride swelled PDMS into any solvent that exceeds the swelling capacity of the polymer. The resultant extract was then analyzed by gas chromatography coupled with mass spectrometry.

The complete extraction procedure is detailed in Figure 1 below. (A) The initial sample containing analytes and co-solvent is inverted to allow contact between the sample and polymer. (B) When adding a co-solvent to the ILE process, the rate of extraction is enhanced by increasing

both total solvent surface area and volume. Analytes are first rapidly sorped into the co-solvent followed by concurrent sorption of the co-solvent and analytes into the polymer phase. The resultant partition ratio will be analogous to that of an aqueous phase and a mixed solvent system. (C) The polymer layer, swollen with a water immiscible co-solvent contains partitioned analyte(s). (D) The back-extraction process consists of the partitioning of the analyte(s) into a suitable solvent from the co-solvent swollen polymer.

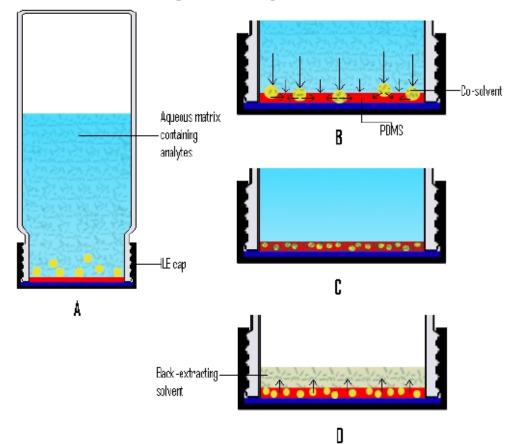

Figure 1: ILE Cap Procedure

Calibration

Calibration spike solutions were composed by diluting appropriate aliquots of Accustandard M-525.2-SV-ASL in a 50:50 mixture of acetone and methylene chloride such that the concentrations of analytes of interest would correlate to a 100mL sample that is extracted with one-hundred percent efficiency. Calibration spikes were then analyzed by GCMS, and the MS response of the quantitation ion of each analyte in the spike was then related to the MS response of the quantitation ion of the internal standard with the nearest retention time, and an average response factor (RF) was assigned to each compound of interest (Equation 1). This response factor was later used to calculate the observed concentration, and subsequently, the extraction efficiency of a processed sample.

Equation 1: Response Factor

$$RF = \frac{(A_x) \cdot (Q_{is})}{(A_{is}) \cdot (Q_x)}$$

Where:

 $A_x = \text{integrated abundance of the quantitation ion of the analyte} \\ A_{is} = \text{integrated abundance of the quantitation ion internal standard} \\ Q_x = \text{quantity of analyte in calibration spike } (\mu g) \\ Q_{is} = \text{quantity of internal standard in calibration spike } (\mu g)$

Data Collection

The observed concentration of an identified compound in an extracted sample was calculated by relating the MS response of the quantitation ion of said compound to the MS response of the quantitation ion produced by a compound used as an internal standard (Equation 2).

Equation 2: Observed Concentration Calculation

$$C_x = \frac{(A_x) \cdot (Q_{is})}{(A_{is}) \cdot RF \cdot V}$$

Where:

 C_x = concentration of analyte in water sample (µg/L) A_x = integrated abundance of the quantitation ion of the analyte A_{is} = integrated abundance of the quantitation ion internal standard Q_{is} = total quantity of internal standard added to water sample (µg) V = original water sample volume (L) RF = mean response factor of analyte from the initial calibration

Additionally, standard deviations and method detection limits (MDL) were determined for all compounds of interest.

RESULTS

Table 1 (below) displays a cross section of analytes of varying volatility, mass, and polarity. This data indicates that ILE has the capability to reproducibly extract a variety of semi-volatile analytes in the sub-nanogram/Liter range from 100 mL drinking and waste water samples.

Compound	True Conc. (μg/L)	Mean Observed Conc. (µg/L)	Relative Standard Deviation (%)	Mean Method Accuracy (% of True Conc.)	MDL (µg/L)

Table 1: Calculating Method Detection Limits

DISCUSSION

Smaller Sample Sizes, Reduced Solvent Usage, Matrix Effects

Current EPA-approved methods for analyzing semivolatiles in water require the use of an entire 1 L sample in order to provide data that is within the parameters that are required by the EPA (MDLs, precision, etc.). The ILE method requires only 100 mL of a 1 L sample to provide precise results and sufficient detection limits. This is possible because the ratio of extract volume to sample volume is identical to that associated with current EPA-approved methods. In current methods, a 1 mL extract is formed from a 1 L sample, whereas in ILE, a 100 μ L extract is composed from a 100 mL sample (both result in a concentration factor of 1,000).

There are a number of advantages involved with this reduction in required sample size. First, in the case of operator error or equipment malfunction, the entire sample is not lost. Additionally, an analyst has the capability to archive an analyzed sample or to analyze the sample under similar conditions to permit verification of data. Last, a sample may be analyzed using a range of co-solvent / polymer combinations to enhance or alter selectivity.

The ILE procedure provides many other distinct advantages over currently accepted and practiced methods for environmental sampling. Both SPE, and especially LLE, involve complex, labor-intensive, multi-step procedures in which each step can introduce errors or loss of analytes.

The ILE procedure is composed of two non laborious steps. Additionally, solvent usage is decreased by factors greater than 100 and 1000 relative to SPE and LLE, respectively.

Many significant problems associated with the SPE method are avoided by ILE caps. ILE caps are immune to clogging by dirty samples, particulates, and viscous samples, and analyte breakthrough is avoided because ILE is an equilibrium reaction. Similarly, problems involved with LLE, such as the formation of emulsions, are avoided.

Co-Solvent Extraction & Sample Cleanup

In this series of experiments, a small amount of methylene chloride was added to each sample as a co-solvent to enhance partitioning from the sample into the polymer extraction medium. Compounds that may have a relatively low affinity for the PDMS may partition into the methylene chloride, which is effectively absorbed into the polymer, causing a sponge-like swelling effect. This co-solvent may be any organic solvent that is both absorbed by the polymer and is immiscible in water.

Different co-solvent/polymer combinations will yield different results, as many analytes may have a greater or lesser relative affinity for different solvents and/or polymers. For example, the appropriate combination of solvent and polymer may enhance selectivity for isolating (non)halogenated analytes, PCBs from other interferents, or polar from non-polar analytes.

The addition of a co-solvent to a sample may also be omitted. Data collected from extractions both with and without co-solvent assistance suggests that some analytes may have a significantly greater affinity for methylene chloride than for either acetone or the PDMS. Because PDMS is capable of absorbing a much greater quantity of methylene chloride than acetone, analytes that retain a high concentration in the methylene chloride through the back-extraction process may yield a lesser MS response than expected. An analyst may also strategically determine his or her back-extracting solvent to enhance or alter specificity as he or she desires.

Additional specificity may be obtained by adding a rinsing or solvent cleanup step prior to the back-extraction of analytes from the polymer coating. This step is composed of rinsing the cap with a water miscible aqueous phase to essentially remove, or clean up, unwanted analytes (this step is common in SPE).

CONCLUSIONS

ILE is a promising new method for extracting organic compounds from aqueous matrices, and has terrific potential for environmental applications. The method consists of a simplified procedure that requires minimal operator effort, reduces solvent usage and allows for the analysis of smaller samples without compromising limits of detection and data precision. The possibilities to alter selectivity through strategic combinations of solvents and polymers will allow an experienced analyst to zero in on a compound, or type of compounds, with incredible ease. Further studies investigating the potential of the method in environmental and other applications are in progress.

Immobilized Liquid Extraction[™] of Drinking or Waste Water as a New Sample Preparation Technique for GC/LC Analysis

Robert H. Wohleb, Ph. D. Wohleb Scientific, Inc. 989 Milton Avenue, Suite 1D

Ferndale, CA 95536

Introduction

- Traditional EPA and Standard Methods to extract organic compounds from water samples are based either on liquid/liquid extraction (LLE) or liquid/solid extraction employing solid phase extraction (SPE) disks or cartridges
- Each technique plagued by shortcomings
 - LLE is laborious, time-consuming, uses solvent excessively, may suffer from emulsions and requires solvent evaporation
 - SPE requires sorbent conditioning, sample concentration, and is impractical when a sample contains particulates
- This study investigates Immobilized Liquid Extraction[™] (ILE) as a novel technique for extracting organic compounds from aqueous environmental samples

Scope of This Study

- Discuss and study fundamental principles of Immobilized Liquid Extraction
 - ILE method, theory and devices
- Demonstrate viability of ILE as a method for preparing aqueous environmental samples
 - Analyse diesel, pesticides and semivolatiles from a variety of aqueous matrices
 - Enhance selectivity
 - Method detection limits
 - Reduced sample size and solvent usage
 - Complex matrix effects

What is ILE?

- ILE utilizes 'surface sorption extraction'
 - Popular 'surface sorptive extraction' systems include Solid Phase Micro Extraction (SPME), Stir Bar Sorbtive Extraction (SBSE) and Open Tube Sorptive Extraction
- Extracting phase immobilized on surface of ILE device
 - Surface may be the septum of a bottle or vial cap, the inner surface of a vial or disposable pipette (tip), or a number of other possibilities
 - True liquid liquid extraction
 - Non-extactable elastomers above T_q

How Does ILE Work?

- Liquid/liquid extraction in which the "organic" phase is immobilized on the surface of an ILE device
 - Similar fundamentals to SPME, SBSE and LLE
 - Equilibrium technique
- Based on preferential sorption of analytes into immobilized sorbent
- Analytes partition from sample matrix into immobilized polymer
 - Optionally, a sample may be diluted with a small amount of solvent, salted out, or acidified to enhance extraction speed or selectivity
- Analytes next desorped from immobilized polymer into a small amount of suitable GC or HPLC solvent

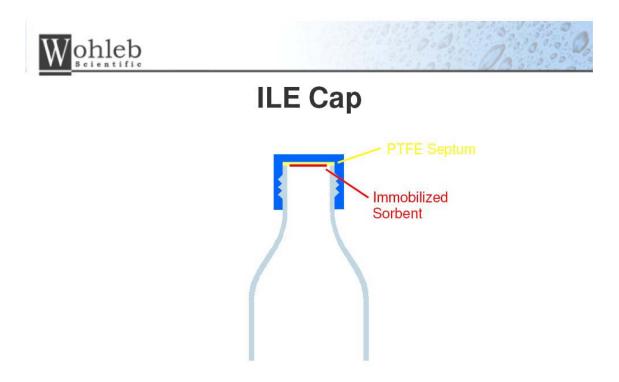

General ILE Method

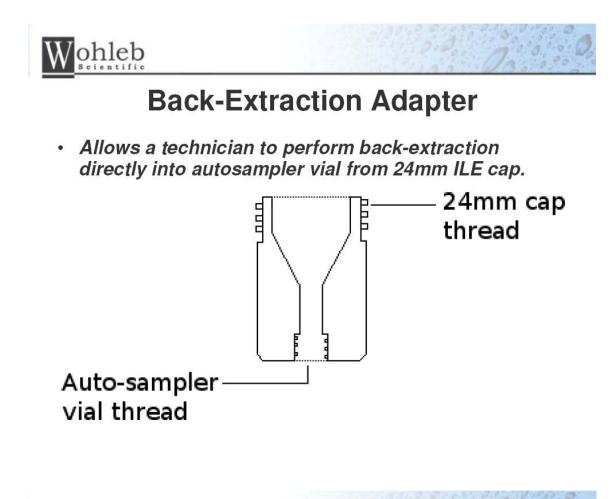

- Two Step Method
 - Extraction
 - · Sorbent of ILE device directly exposed to aqueous sample
 - Targeted compounds partition from sample into immobilized phase until equilibrium is reached
 - Note: agitation will accelerate this process
 - Back-Extraction
 - Analytes desorped from immobilized phase into small amount of suitable solvent
 - Resultant extract ready for GC or HPLC analysis

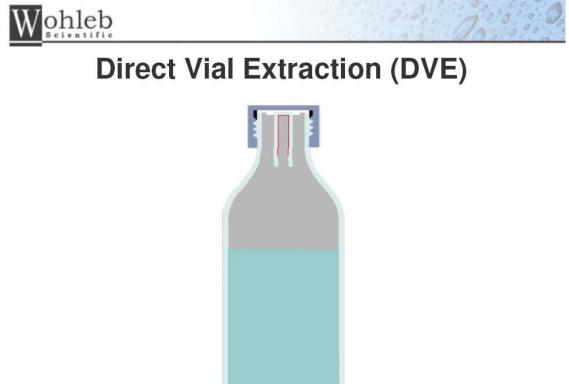

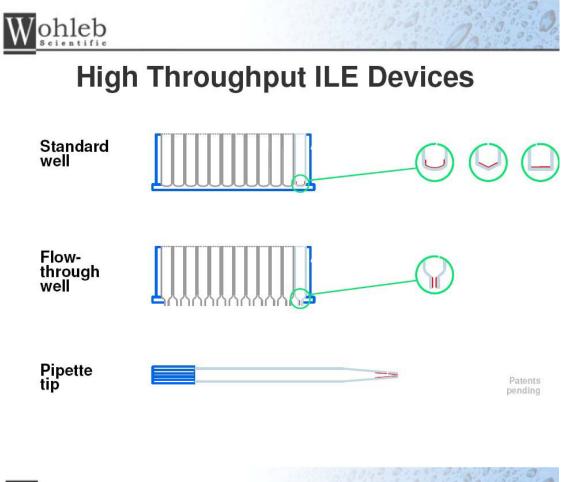

ILE Devices

- ILE Cap
- ILE Direct Vial Extraction
- High Throughput ILE Devices
- Back Extraction Adapter

ILE Theory

• From only analyte specific partition ratios and the relative ratios of each of the phases (sample, polymer, residual solvent) one can easily calculate his or her expected total extraction efficiency:

$$% \text{Recovery} = \left(100 \cdot \frac{\frac{K_{Polymer/Sample}}{\beta_1}}{1 + \frac{K_{Polymer/Sample}}{\beta_1}} \cdot \left(100 \cdot \frac{\frac{K_{Solvent/Polymer}}{\beta_2}}{1 + \frac{K_{Solvent/Polymer}}{\beta_2}}\right)$$

Extraction Efficiency
$$\beta_1 = \frac{V_{Sample}}{V_{Polymer}} \qquad \beta_2 = \frac{V_{Polymer}}{V_{Solvent}}$$

Enhancing Selectivity

- Choice of extracting phase (non-polar to polar)
- Use and/or choice of co-solvent
- · Adjusting pH of sample
- Salting a sample

Enhancing Selectivity

- · Series of experiments
 - 20mL water samples spiked with a pesticide mix (525) such that each targeted analyte was at a concentration of 25 μg/L
 - Samples extracted using ILE caps
 - Effects of phase selection, co-solvent use, pH adjusting and sample salting investigated

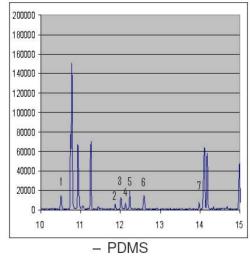

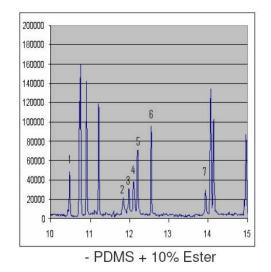

- ILE phases tested:
 - PDMS
 - Phenyl Siloxane
 - 50/50 PDMS/Fluorosilicone blend
 - Carbon Black
 - PDMS +10% acrylate ester
 - Nitrile
 - PEG
 - PDMS/porous polymer blends

Phase – PDMS vs. PDMS + 10% Ester

- 1 Propachlor
- 2 Atraton
- 3 Prometon
- 4 Atrazine
- 5 Propazine
- 6 Pronamide
- 7 Simetryn

Phase Selection Trends

- Trends
 - MS response was dramatically increased with the PDMS + 10% ester for polar compounds that do not partition well into PDMS
 - Specifically, polar compounds that do not generally partition well into PDMS are attracted to the acrylate ester
- The availability of multiple phases that range in polarity allows an analyst to extract compounds that may otherwise be difficult, or impossible, using exclusively a PDMS phase

Selecting and Using a Co-Solvent

- ILE polymers absorb solvents
 - ILE polymers swell when exposed to solvents
 - The polymer effectively acts like a sponge, soaking up the solvent
 - Each polymer has solvent-specific swelling capacities
- An appropriate co-solvent must be both sufficiently absorbed by the polymer being used, and water immiscible
 - The quantity of co-solvent used should be no greater than the swelling capacity of the polymer

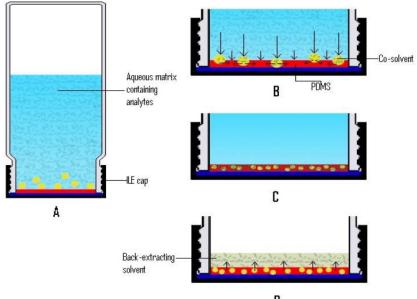

Advantages of Co-Solvent Usage

- Rate of extraction is enhanced by increasing both total solvent surface area and volume
 - Analytes first rapidly sorped into co-solvent, followed by concurrent sorption of co-solvent and analytes into polymer phase
- Different co-solvent/polymer combinations will yield different results
 - Ex: isolating (non)-halogenated analytes, PCBs from other interferants, or polar from non-polar analytes.

Co-Solvent Assisted Extraction

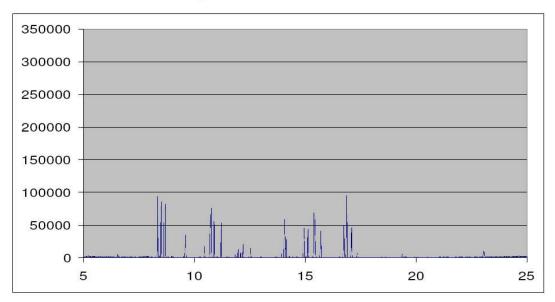

An Example

- The following slides depict the enhancement that resulted from introducing hexane as a co-solvent with a phenyl ILE cap
 - MS response was significantly increased across the board when the co-solvent was used
 - Eleven additional compounds were detected at quantifiable levels

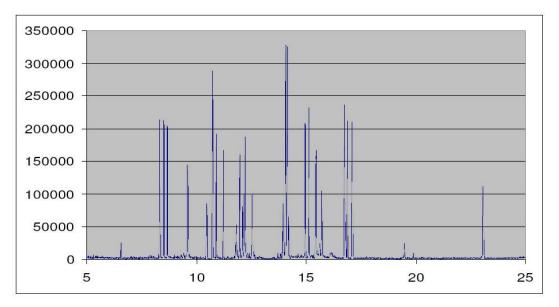

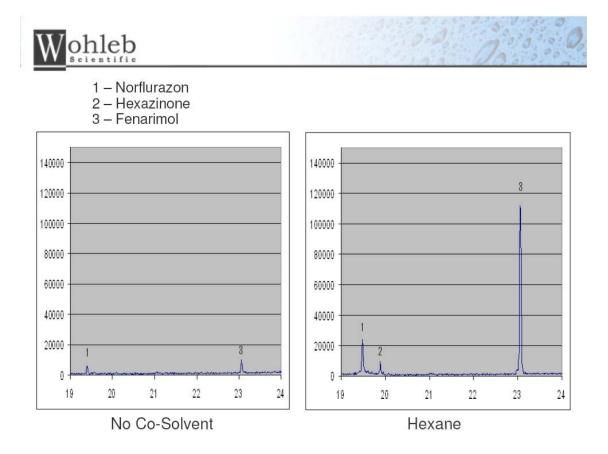

Phenyl / No Co-Solvent

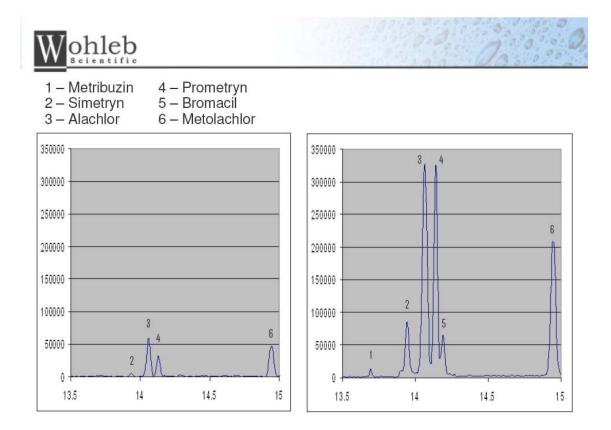

Phenyl / Hexane

22nd Annual National Environmental Monitoring Conference

Co-Solvent Summary

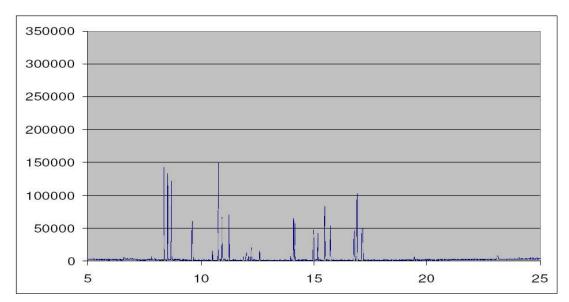

- The possibilities to alter selectivity through strategic combinations of solvents and polymers allows an experienced analyst to zero in on a compound, or type of compounds, with incredible ease
 - Each targeted analyte in the pesticide mix was reproducibly extracted with at least one polymer/co-solvent combination

- The following chromatograms display the effect of sample salting on the ILE process
 - Two 20mL samples were spiked with pesticides and extracted using a PDMS ILE cap and methylene chloride as a co-solvent
 - One sample had 2 grams of table salt added

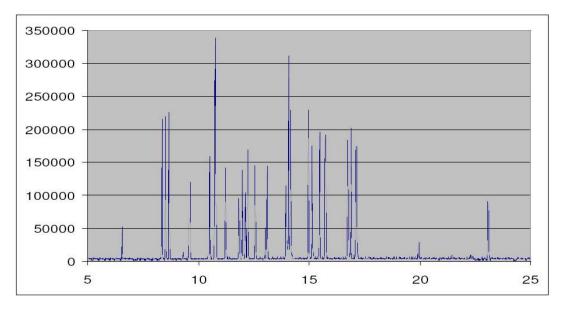

PDMS / Methylene Chloride

Wohleb

PDMS / Methylene Chloride + Salt

Sample Salting

- Trends
 - All compounds in the pesticide mix were detected in salted sample
 - MS response was increased for most compounds of interest with sample salting
 - The unsalted sample yielded significantly higher extraction efficiency with only four compounds
 - Trifluralin (+145%), Butachlor (+25%), Cycloate (+18%), Butylate (+8%)
 - Of 37 compounds in the pesticide mix, these are 4 out of the 5 compounds with highest Octanol:Water partition ratios

Adjusting pH (Semi-volatiles)

- Positive effects of sample acidification were realized in the extraction and analysis of a semi-volatile standard mixture in water
 - All PCB's extracted more efficiently from acidified samples (increases ranged from 1-31%)
 - The following table displays significant increases and decreases due to sample acidification (pH ~ 1.5)

COMPOUND	+/-	Log K _{o/w}	COMPOUND	+/-	Log K _{o/w}
Acenaphthalene	-90%	3.94	Chrysene	43%	5.81

Semi-Volatiles from Drinking Water

- · Series of experiments
 - 100mL water samples spiked with a semivolatile mix where each analyte was at a concentration of 0.5 μg/L
 - Samples were extracted using methylene chloride as a co-solvent

Semi-Volatiles from Water

Method Detection Limits

- ILE Caps tested for conformity to EPA protocols
 - Method Detection Limits were determined using the procedure outlined in Chapter 1 of SW-846
 - Sub-PPB Limits of Quantification were
 accomplished for 21 of 32 compounds tested

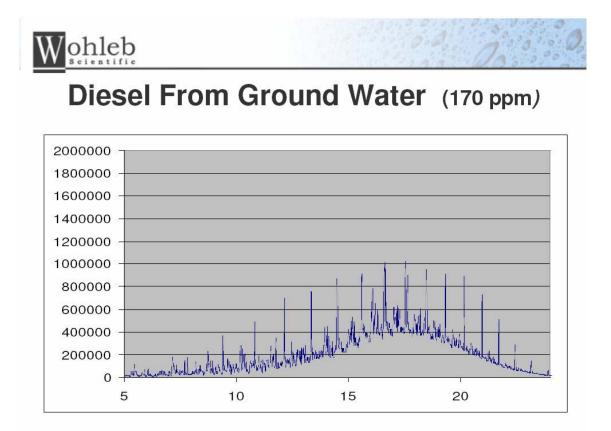

Method Detection Limits

Compound	True Conc. (μg/L)	Mean Observed Conc. (μg/L)	Relative Standard Deviation (%)	Mean Method Accuracy (% of True Conc.)	MDL (µg/L)
Acenaphthalene	0.5	0.37	8.3	73.9	0.17
Benzo(b)fluoranthene	0.5	0.48	6.8	95.6	0.14
Benzo(g,h,i)perylene	0.5	0.50	28.2	99.9	0.57
2-Chlorobiphenyl	0.5	0.49	6.3	97.1	0.13
2,3- Dichlorobiphenyl	0.5	0.57	1.2	113.1	0.02
Dibenz(a,h)anthracene	0.5	0.48	4.7	96.4	0.09

Diesel From Ground Water

- ILE Caps were tested for their ability to extract diesel from water
 - 20mL of water was spiked with diesel at a concentration of 170 ppm and extracted with a PDMS ILE cap (no co-solvent)

Further Discussion

- Smaller samples
- Reduced solvent usage
- Matrix effects
- Field extractions

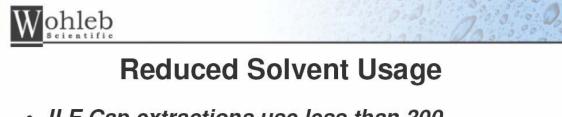

Analyze Smaller Samples

- Current EPA-approved methods for extracting diesel, pesticides, PCBs and semivolatiles from water require the use of an entire 1L sample
- ILE requires that only 100mL of a 1L sample be used to provide data within the parameters required by the EPA (MDL's, precision, etc.)
- Concentration effects
 - EPA methods: 1L sample to 1mL extract
 - ILE: 100 mL sample to 100µL extract
 - Same 1000:1 concentration factor
 - A large volume injector would increase sensitivity and/or reduce sample size further

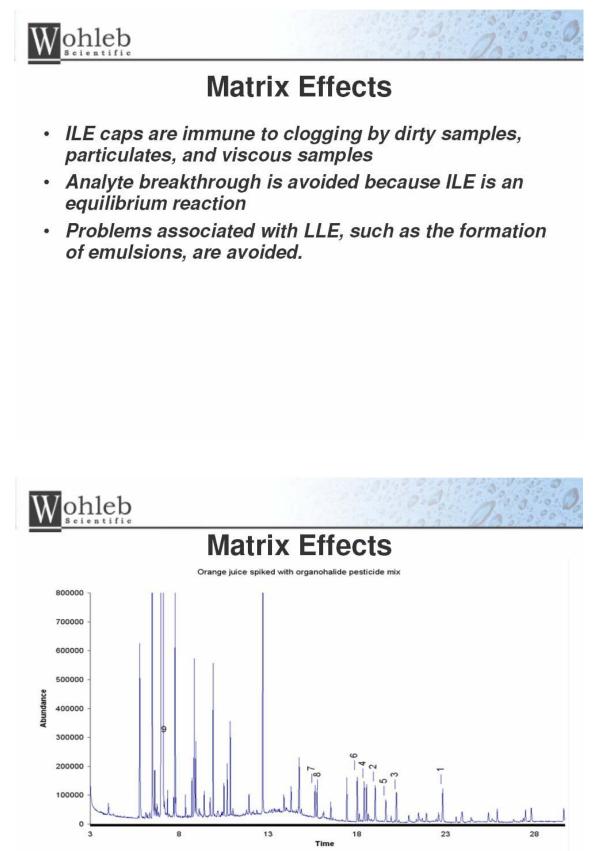

Analyze Smaller Samples

- Advantages
 - Operator error or equipment malfunction no longer results in loss of entire sample
 - Samples may be extracted and archived for later analysis
 - Duplicate analyses permit data verification
 - A sample may be analyzed under a variety of conditions (different phase, co-solvent, pH & etc.

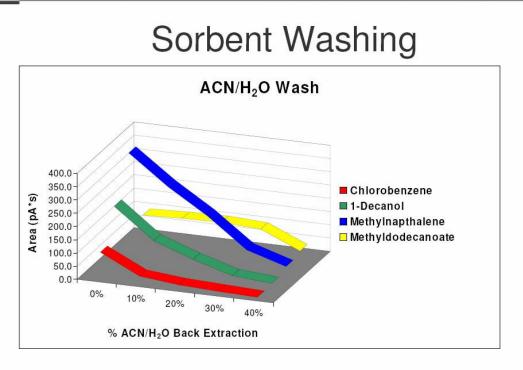

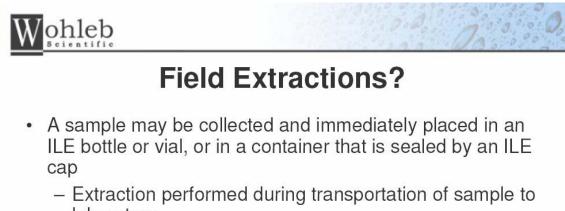

- ILE Cap extractions use less than 300
 microliters of solvent
 - Solvent usage decreased by factors greater than 100 and 1000 relative to SPE and LLE, respectively
 - Save money on purchase and disposal of solvents

Accelerated Solvent Extraction (ASE) as a Innovative Sample Preparation Technique for Conventional and Emerging Pollutants in Environmental Samples

Sheldon Henderson, Eric Francis, Richard Carlson and Bruce Richter Dionex Corporation

ABSTRACT

Accelerated solvent extraction (ASE) is an innovative approach to liquid-solid extraction. It is accepted under Method 3545A for the extraction of conventional environmental toxins such as PCBs, dioxins, PAHs, diesel range organics and chlorinated pesticides. This technique uses elevated temperature and pressures to achieve analyte extractions from solid or semi-solid matrices in about 15 minutes and with small volumes of solvents. For example, a 10-g sample can be extracted in about 12 minutes and with about 15 mL of solvent.

There has been increasing concern from scientists and public health officials about emerging pollutants such as brominated flame retardants, perchlorate, hexavalent chromium and perfluorooctanoic acids. These compounds are derived from various sources in the manufacturing of consumer electronics and consumer products. These contaminants may also come from chemical or industrial manufacturing sources. These compounds have been shown to enter the ecosystems via disposal into landfills and have been found in groundwater, soils and sediments, plant and animal tissues and eventually into the human system.

Traditional methods such as Soxhlet or shakers have been used to extract samples containing these toxins. These methods require long periods of time (16 hours) and large volumes of solvent or aqueous buffers (300 mL) and large amounts of manual sample handling and manipulation in preparation for analysis. ASE can perform these extractions in short periods of time and with small amounts of solvent. This presentation will discuss the use of ASE and ASE compatible techniques such as in cell clean-up for the effective sample preparation of several environmental matrices, including soils, sediments, plant or animal tissues, for analysis of various conventional and emerging contaminates. Comparisons of analyte recovery and sample handling efforts to traditional methods of extraction will be presented.

Accelerated Solvent Extraction (ASE®) as an Innovative Sample Preparation Technique for Conventional and Emerging Pollutants in Environmental Samples

Sheldon Henderson, Eric Francis, Richard Carlson, Brett Murphy and Bruce Richter Dionex Corporation, Salt Lake City, Utah

Summary Slide

Accelerated Solvent Extraction (ASE®) as an Innovative Sample Preparation Technique for Conventional and Emerging Pollutants in Environmental Samples

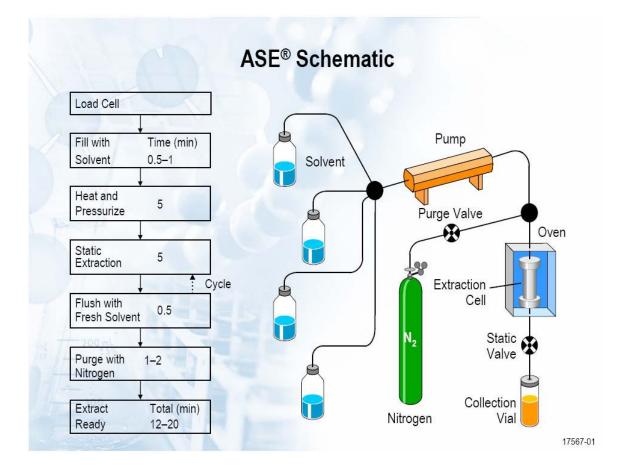

Sample Preparation Issues

- Sample handling is the single biggest source of errors
- Single biggest bottleneck in an analytical process
- All laboratories are being asked to do more with less resources
- Time is money
- Costs of solvent purchase and disposal are increasing
- Dionex has developed ASE[®] compatible techniques to address these issues

22863

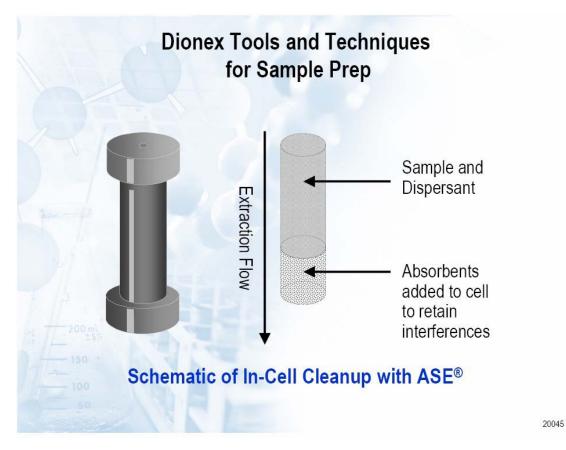

What Is ASE[®]?

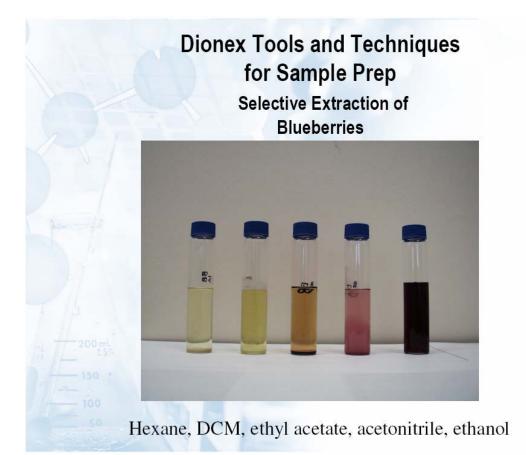

- An automated extraction technique that uses liquid solvents and solvent mixtures
- Extracts solid or semisolid samples
- Uses elevated temperatures (40–200 °C) and pressures (500–3000 psi)
- Use of elevated temperatures and pressures accelerates the extraction process

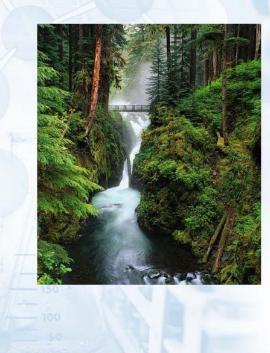

Environmental Matrices Investigated

- Soils
- Sludges
- ♦ Sediments
- Plant and animal tissues
- Air Samples
 - Quartz filters
 - Tenax resins
 - Charcoal adsorbents
 - PUF and XAD resins
- Essentially all solid or semi-solid matrices analyzed for environmental contaminants

ASE Environmental Applications (Conventional Pollutants)

- US EPA Method 3545A
 - Pesticides and Herbicides
 - Semi-volatiles and PAHs
 - PCBs
 - PCDDs and PCDFs
 - TPH (DRO)

- Explosives
- Organotin and organoarsenic compounds
- ♦ Ionic materials

ASE Applications (Emerging Pollutants)

- Perchlorate
 - Explosives and Rocket Propellants
- PBDE
 - Flame Retardants
- Chrome (VI)
 - Curing agent
- Perfluorooctanoic acid
 - Oil or water repellant

TUESDAY, AUGUST 29, 2006 CONCURRENT SESSIONS

Chemical Speciation -- As

ANALYZING ARSENIC SPECIES IN SEAFOOD

Chamberlain, Isa; EPA Region 10 Laboratory

Arsenic, a known carcinogen and toxin at low concentrations, is a naturally occurring and manintroduced element found in all environmental matrices (soil, water, and air), as well as living matter. Therefore, arsenic exposure assessment requires evaluation of the relative contribution of both media (water, food, etc.) and routes of exposure (ingestion, inhalation, dermal). Seafood is known to contain high levels of arsenic. EPA Region 10 seafood consumption rates are above average national values due to a large population of Native American and Alaska Native. In addition, the Asian and Pacific Islander population in the Puget Sound Area favors shell fish species and bottom fish which ingests sediment and does not solely filter marine water. Thus, Superfund and RCRA Clean-Up goals in the Puget Sound are derived from food modeling risk assessments. However, understanding the risk from eating seafood is a complicated issue, as different chemical forms of arsenic vary significantly in their toxicity.

This is a procedure for extracting different forms or species of arsenic from seafood using tetramethyl ammonium hydroxide (TMAOH). The extract is then analyzed using ion chromatography (IC) to separate the species prior to detection by inductively coupled plasma – mass spectrometry (ICP-MS). The types of seafood for which this method has been developed are seaweed, finfish, and shellfish. The species separated and analyzed by this method are: arseneous acid (As3+), arsenic acid (As5+), monomethylarsonic acid (MMA), dimethylarsinic acid (DMA), arsenobetaine (AsB), arsenocholine (AsC), trimethylarsine oxide (TMAO), tetramethylarsonium ion (TMA) and arsenosugars [As(328), As(392), As(408), etc.]. This procedure allows for the calculation of mass balance and the effectiveness of the arsenical extractions enabling the data users to more accurately estimate exposures.

A Procedure for Extracting and Analyzing Arsenic Species in Seafood

By Stephanie Le, Isabel Chamberlain, and Katie Adams

Why our interest in Arsenic Speciation analysis?

 Two major sources of arsenic exposure are drinking water and dietary ingestion.

 Seafood typically contains high levels of arsenic

 In Region 10 (Alaska, Idaho, Oregon, and Washington), seafood consumption rates are often well above national values.

Examples of Arsenic Species:

Most Toxic
Inorganic Arsenic (As III and As V)

MMA and DMA

Least Toxic AsB and Arsenosugars

Risk Assessment...

How much of the toxic species are present

- In different seafood types?
- In different seafood sources?

ARSENIC SPECIES DETERMINATION

Pohl, C.A.; Dionex Corporation Slingsby, R.W.; Dionex Corporation

Arsenic is ubiquitous in the environment in various forms, including inorganic and organic compounds and trivalent and pentavalent states. In general, methylated and other organoarsenicals are less toxic than inorganic arsenic, and trivalent arsenic is considerably more toxic than pentavalent arsenic. So arsenic can be classified as highly toxic when in the inorganic form, and as innocuous to human when present as certain organo-arsenicals. The USEPA has classified inorganic arsenic as a known human carcinogen, but arsenobetaine, a water soluble pentavalent organoarsenical, is very stable, metabolically inert, and relatively nontoxic and thus poses little toxicological risk to the organism or its consumers. Therefore the speciation of arsenic in various samples is important to assess the risk to human health.

In this study, ion chromatography has been coupled with electrospray mass spectrometry (IC-ESI-MS) to quantitatively determine five arsenic species. We will present a method for the determination of Arsenite(AsIII), Arsenate(AsV), Monomethylarsonic acid(MMA), Dimethylarsonic acid(DMA) and Arsenobetaine(AsB) using IC-ESI-MS. Relative to ICP-MS, the competitive method, ESI-MS has the advantage of providing mass-to-charge information for each arsenic species. Arsenite and arsenate are retained by anion exchange at high pH and arsenobetaine, monomethylarsinic acid and dimethylarsonic acid are retained at acidic pH. The combined analyses of these analytes can be accomplished using a dual IC system comprising anion exchange and cation exchange columns, or using a mixed phase column.

Since these five species have pKa values ranging from 2-9 and arsenobetaine is amphoteric, this analyte set represents a significant analytical challenge in obtaining good chromatographic retention for all species, especially in complex food matrices. We report progress on a new mixed phase analytical column as well as several hardware configurations that allow the determination of these five arsenic species in a single analysis using an ESI-MS compatible eluent system. Presently, there are no ESI-MS compatible chromatography methods that provide good retention of all five arsenic species.

Separation and Detection of Arsenic Species using Dual Selectivity IC-MS

Rosanne W. Slingsby¹, Rida Al-Horr¹, Christopher A. Pohl¹, and Joung Hae Lee² ¹Dionex Corporation; ² Korea Research Institute of Standards and Science

ABSTRACT

In this study, two ion exchange selectivities are combined using a dual ion chromatograph that is coupled with electrospray mass spectrometry (IC2-ESI-MS) to determine anionic, cationic and zwitterionic arsenic species. This scheme provides adequate chromatographic retention of all arsenic species while also providing detection using electrospray ionization mass spectrometry for structural information. We present a method for the determination of Arsenite(AsIII), Arsenate(AsV), Monomethylarsonic acid(MMA), Dimethylarsonic acid(DMA) and Arsenobetaine(AsB) using IC2-ESI-MS. Since these five species have pK_a values ranging from 2-9 and arsenobetaine is amphoteric, this analyte set represents a significant analytical challenge in obtaining good chromatographic retention for all species. Relative to ICP-MS, the competitive detection method, ESI-MS has the advantage of providing mass-to-charge information for each arsenic species. Compared to other chromatography methods, this method provides good retention of all five species in one analytical method. The combined analyses of these analytes can be accomplished using a dual IC system comprising anion exchange and anion/cation exchange separations that are delivered sequentially to the mass spectrometer in one data file.

INTRODUCTION

Arsenic is ubiquitous in the environment in inorganic and organic compounds and trivalent and pentavalent states. In general, methylated and other organo-arsenicals are less toxic than inorganic arsenic, and pentavalent arsenic is considerably less toxic than the trivalent state. The USEPA has classified inorganic arsenic as a known human carcinogen, but arsenobetaine, a water soluble pentavalent organoarsenical, is very stable, metabolically inert, and relatively nontoxic and thus poses little toxicological risk to the organism or its consumers [1,2]. The speciation of arsenic in various samples is important to assess the risk to human health.

The use of reversed phase columns with ion-pairing eluents and separate anion exchange and cation exchange systems for the separation of As(III), As(V), MMA, DMA, AsB and other arsenic species have been reported [3,4,5]. Most of the mobile phases are incompatible with electrospray ionization-MS. Use of a combination of anion exchange and cation exchange columns is necessary to retain this mix of arsenic species since this group includes anions, cations and the amphoteric arsenobetaine. Separation schemes that do not include both functionality columns show at least one arsenic compound in or near the void volume, thus not separated from matrix components. In general, the earliest eluting arsenic species, usually arsenite or arsenobetaine depending on the retention mechanism, is barely retained from the void and therefore is susceptible to ionization suppression from sample matrix components when ESI is used.

In the present paper we present an analytical scheme that combines gradient anion exchange with mixed mode anion/cation exchange isocratic elution so that all five arsenic species are well retained and separated in one analytical run. The mobile phases are compatible with ESI-MS detection.

Experimental

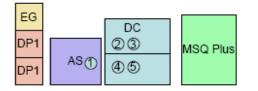

Instrumentation - The ion chromatograph used in this work was the Dionex ICS 3000 (Dionex Corp., Sunnyvale CA USA) that included a Dual pump module with two analytical pumps (DP1, DP1), and eluent generator (EG0), a conductivity detector (CD), autosampler that included a diverter valve (AS) and a chromatography compartment (DC) that included two high pressure valves and two 6-port injection valves. The mass spectrometer was the MSQTM PLUS single quadrupole mass spectrometer (Dionex and ThermoFinnigan, Santa Clara, CA USA). It has a pneumatically- and thermally-assisted electrospray ion source. Chromeleon® 6.8 software (Dionex) was used for all instrument control, data collection and data reduction.

Chromatography Supplies and Chemicals - The IonPac® AS18 (250 x 2-mm I.D.) and IonPac CS5A (250 x 2-mm I.D., Dionex) analytical columns were used. The IonPac AC15 (50 x 2-mm I.D.) column was used in place of a guard column with the CS5A column in order to increase the anion exchange capacity in the mixed mode CS5A column. An eluent generator was used to produce potassium hydroxide eluent in-line for the AS18 column. A continuously regenerated anion trap device, CR-ATC (Dionex), was used to remove trace level anions from the source water. Formic acid eluent for the cation system was prepared by dilution from formic acid (96%, Sigma Aldrich). Eluent suppression for the anion work was accomplished with a continuously regenerated electrolytic suppressor, the ASRS® MS. The cation system did not use a suppressor. The water for regeneration of the suppressor and operation of the eluent generator and anion trap device was supplied by a pressurized reservoir.

Arsenic (III) and Arsenic (V) stock solutions were obtained from SPEX CertiPrep (Metuchen, NJ, USA). Disodium methylarsonate (MMA) was obtained from Chem Services (West Chester, PA, USA) and the cacodylic acid (DMA) was obtained from Sigma Aldrich (Milwaukee, WI, USA). The arsenobetaine was purchased from the European Commission (Reference Material No. 626). Deionized water (18 Megohm-cm, Milli-Q, Millipore, Cambridge, MA) was supplied to the eluent generator, CR-ATC and suppressor, and was used to prepare all standards and samples.

Hardware Setup - Figure 1 shows the flow diagram of the dual IC2-MS system with shared autosampler, chromatography module and mass spectrometer. The instrument and chromatography conditions are summarized in Table 1. All system control and calculations were accomplished using Chromeleon® 6.8 software (Dionex). Briefly, two injections are made sequentially into two column sets, 15 minutes apart, and the detection data from the conductivity and ESI-MS detectors is collected in one data file.

dimethylarsinic acid, 1 μg/L	+	139	80
5. monomethylarsonic acid, 10 µg/L	+	141	60

Results and Discussion

Anion exchange and mixed mode anion-cation exchange separations were combined in one analytical method to provide for substantial retention of a model group of five arsenic species that includes anions, cations and a betaine. The overall method illustrates the ability to separate a suite of analytes with diverse acid/base properties from matrix ions with flexibility by design of the eluting conditions.

Anion Exchange - The IonPac AS18 column is a latex-based, hydroxide selective anion exchange column with 75 uEq/column in the 250 x 2-mm format. The anion exchange phase is selective for hydroxide because the quaternary ammonium anion exchange sites bear an alkanol group that increases the hydration of the phase. Hydroxide selectivity is important because it allows use of hydroxide eluting ion that can be neutralized by a cation exchange suppressor (to water) so that the mobile phase entering the ESI-MS contains only water rather than a nonvolatile chemical. The selectivity of the AS18 also allows elution of the trivalent arsenate ion while still retaining arsenite. The monomethylarsonate has intermediate selectivity on this column but is well separated from common sample matrix anions including chloride and sulfate. Chloride is well separated from arsenite as well, which is also important since chloride can cause significant signal suppression of co-eluting analytes.

Mixed Anion/Cation Exchange - Arsenobetaine (AsB) is a zwitterion so the best opportunity for retention is as a cation at acidic pH. Dimethylarsinic acid (DMA) has a pKa of about 6.2, which allows it to cross the cation exchange membrane of the suppressor during the neutralization process. This means that the DMA cannot be determined using the AS18 system. These two analytes separately require cation exchange and anion exchange with no suppression for analysis. The IonPac CS5A column is a mixed mode anion/cation exchange column with 10 µEq/column of anion exchange capacity and 5 μ Eq/column of cation exchange capacity. This means that both anions and cations are retained on the CS5A phase and that an eluent such as formic acid supplies formate as the anionic eluting ion and hydronium ion as the cationic eluting ion. Chloride elutes very close to arsenobetaine using a CS5A column. Sodium chloride is an important matrix consideration because many of the potential samples for the method, e.g. seaweed, fish, are derived from the ocean. The separation of chloride from arsenobetaine is not adequate and signal suppression is observed on the SIM +179 channel during the elution of chloride. The additional anion exchange capacity in the form of an AC15 column added enough retention of the chloride to allow adequate separation of chloride and arsenobetaine as shown in Fig 2.

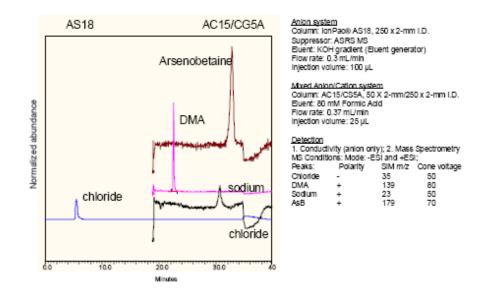

Figure 2: Improved detection of arsenobetaine using additional anion exchange capacity

Detection - In the gas phase of ESI-MS, most of the arsenicals can be detected as anions, as cations, as M[°], M+H, M+H,xH2O etc. or as fragments. Detection conditions for each analyte were compared and optimized to provide the lowest detection limits within the capability of the single quadrupole mass spectrometer. Table 2 summarizes both the chromatographic retention requirements and the optimized detection conditions for the arsenicals. Figure 3 shows the separation and detection of the arsenic standards using the conditions provided in Table 1. Arsenite is retained by anion exchange on the AS18 column (in the void volume of the AC15/CS5A system) and can be detected as the H2AsO3 ion or as the AsO2 ion with better sensitivity. Arsenate is retained by anion exchange on both ion exchange systems and is detected with the best sensitivity as the H2AsO4 ion. It can also be detected as an acid-water adduct in positive mode at m/z 179. Arsenobetaine is protonated in 80 mM formic acid eluent and is therefore retained by cation exchange. It is detected as a cation since the As bears a permanent positive charge. The monomethylarsonate is retained as an anion on the AS18 column but is detected with good sensitivity as the protonated species using positive polarity ESI. Likewise the DMA is retained as an anion and detected as a cation but since its pKa precludes the use of a suppressor it is determined using the AC15/CS5A system. Table 3 provides the linearity over the range of 5-100 µg/L and reproducibility values in water obtained using this method. The minimum detection limits were calculated using external standard quantification since internal standard are under development. The MDL calculation used seven replicates and the standard Student T test calculation. Quantification using internal standards is preferred and often necessary using ESI-MS detection and is the topic of another paper.

SUMMARY

This paper provides an ion exchange-based chromatography scheme that offers good retention and separation of arsenicals having anionic, cationic and zwitterionic properties. The scheme is compatible with electrospray ionization- MS detection.

Outline

- Why Is There Continued Interest in New Methods for Arsenic Speciation?
- What Is the Analytical Challenge?
- How Does "Dual" IC2-ESI-MS Address These Needs?
- Description of the Chemistries and Results to Date
- What About Use of Internal Standards?
- What About Sample Preparation?
- Real World Samples

Arsenic in the Environment

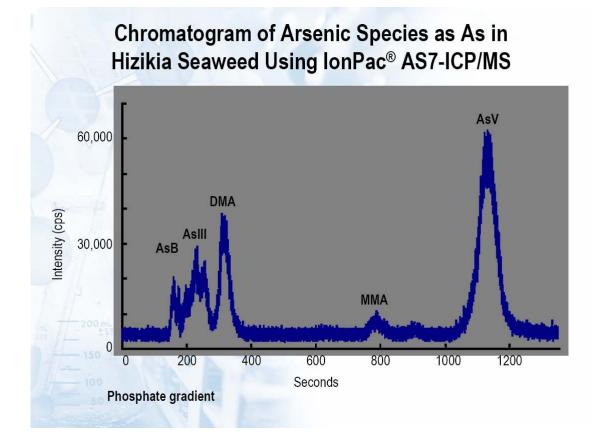

- Naturally-contained in bedrock and enters the drinking water supply
- Single most important environmental contaminant (Anal. Chem., Jan. 2004)
- Some arsenic species are not toxic
- WHO and USEPA MCL = 10 ppb
- Seawater contains about 3 ppb
- Speciation and identification of arsenic species are needed along with low detection limits

Major Arsenic Species in the Environment

1	Arsenite (As [⊪])	Arsenate (As ^v)	Monomethylarsonic Acid (MMA ^v)	Dimethylarsinic Acid (DMA ^v)	Arsenobetaine (AsB)
	-ESI	-ESI	+ESI	+ESI	+ESI

- 11	ОН	OH	ОН	OH	CH ₃
Æ	рКа = 9.29	рКа ₁ = 2.26 рКа ₂ = 6.76	рКа ₁ = 3.6~4.1	pKa = 6.2	рКа = 2.2
12	100		-		

- HPLC/ICPMS using multiple columns offers ng/kg detection limits as As (75 amu)
- HPLC/HG-AFS provides very low detection limits for arsenic species that can form gaseous hydrides with borohydride: arsenite, arsenate, MMA, and DMA
- ESI-MS has been applied to the identification of arsenosugars
- No quantification standards in literature using ESI-MS

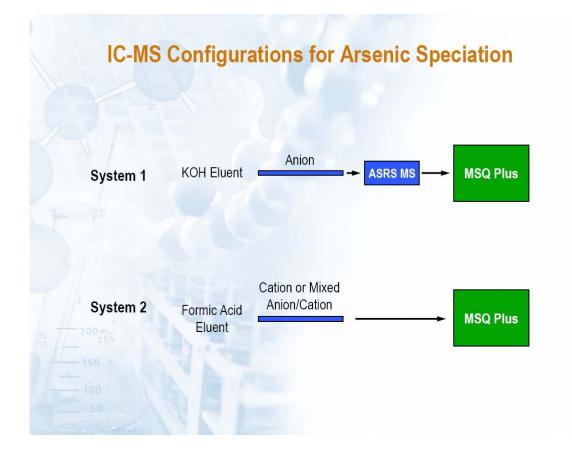

The Analytical Challenge

- Arsenic species include anions, cations, and amphoteric compounds
 - Arsenite, arsenate, monomethylarsonic acid, dimethylarsinic acid, arsenobetaine
 - Arsenosugars
- pK_a values cover the range of 2–9
- DMA crosses the ion exchange membrane in an IC suppressor
 - MMA and DMA are best separated as anions but best detected by +ESI
- Sodium, chloride and other common matrix ions interfere with detection of co-eluting analytes
- One analytical run desirable
 - Structural information with detection limits below 10 ppb desirable
 - Internal standard quantification is desirable

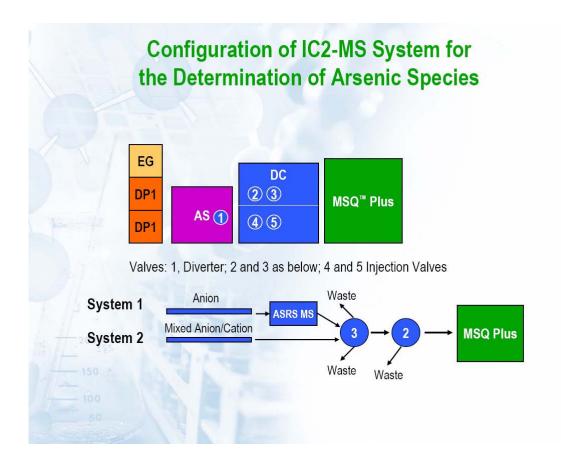

Possible Separation Chemistries for Arsenic Speciation

- Anion exchange
- Cation exchange
- Ion exchange and another retention mechanism
- Mixed anion/cation exchange

Analytical Needs for the Separation and Detection of Five Arsenic Species

Monomethylarsonic Acid (MMA ^V)	Anion Exchange (with Suppressor)	SIM 141, Pos	CH ₃ AsO(OH) ₂ .H⁺	
Dimethylarsinic Acid (DMA ^v)	Anion Exchange (No Suppressor)	SIM 139, Pos	(CH ₃) ₂ AsO(OH).H ⁺	
Sodium	Cation Exchange	SIM 23, Pos	Na⁺	
Chloride	Anion Exchange	SIM 35, Neg	CI-	

Mixed Anion/Cation Exchange Selectivity

IonPac CS5A

- Latex-based
- Mixed mode anion/cation exchange
- 10 µEq/5 µEq per column capacities
- Formic acid eluent

IonPac AC15

- Latex-based anion exchange
- Low hydrophobicity
- Alkanol quaternary ammonium functionality similar to the CS5A selectivity
- 2.2 µEq/column capacity
- Adds anion exchange retention without adding cation exchange capacity

Detection of Ions Using ESI-MS

- ESI-MS provides detection at *m/z* ratio
 - Structural information
 - Higher background than ESI-MS/MS especially in complex matrices
- ESI-MS requires volatile eluent systems
 - Formic acid provides formate as an anionic eluting ion and hydronium ion as a cationic eluting ion
- Ion chromatography suppressors provide desalting as long as the analytes remain charged
 - Can use alkali hydroxide eluent systems
 - Background entering ES interface has very low ionic strength

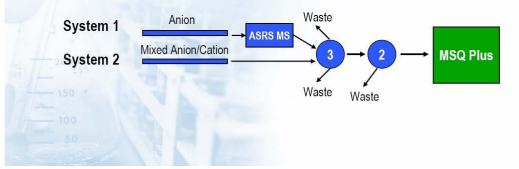

IC2-MS Hardware/Software Configuration for Arsenic Speciation

- ICS-3000 Ion Chromatograph
 - Autosampler can inject into two injection valves in one method
 - » Software control for sequential injection
 - » Diverter valve selects one of two injection valves
 - Data from two injections can be collected into one data file
 - Using two separation chemistries provides maximum selectivity control to handle matrix and many analytes

Configuration of IC2-MS System for the Determination of Arsenic Species

Valves: 1, Diverter; 2 and 3 as below; 4 and 5 Injection Valves

IC2-MS Conditions for Determination of Arsenic Species

Anion System

Column: IonPac® AS18, 250 x 2 mm I.D. Suppressor: ASRS® MS Eluent: KOH gradient (eluent generator) Flow Rate: 0.3 mL/min Inj. Volume: 100 µL

Extraction Method Used for Hizikia fusiforme Seaweed

- 1. 0.5 g of the dried sample was placed in a polyethylene beaker
- 2. 20 mL of 75/25 methanol:water was added
- 3. The whole was homogenized for 24 hours using a shaker unit
- 4. The mixture was maintained at 20 °C for four hours in an ultrasonic unit
- 5. The sample was centrifuged for 25 min at 8000 rpm, and decanted into 100 mL volumetric flask
- 6. The residue was washed with DI water and filtered through a 20 μm filter paper
- 7. The filtered sample (6.) was mixed with the decanted sample (5.) in the 100 mL volumetric flask, the volumetric flask filled with water to the mark

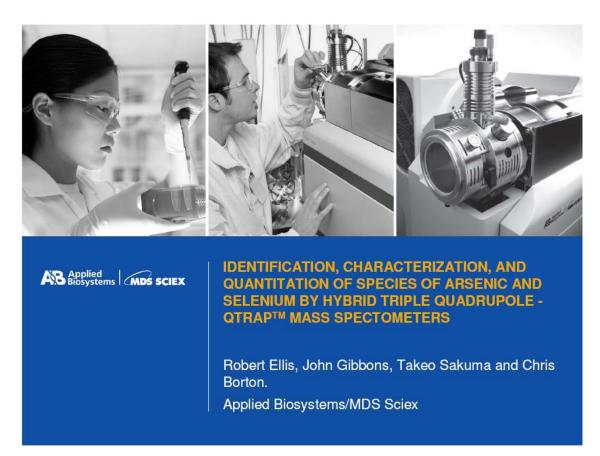

ESI-MS/MS Detection of 10 ppb Arsenite Spiked into Hizikia fusiforme Seaweed Extract

Summary

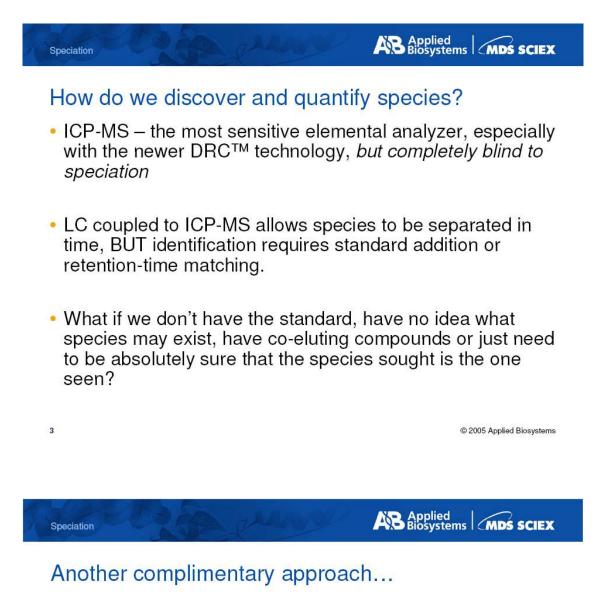

- New, broad-range separation scheme to optimize retention and separation of arsenic species
- Use of ESI-MS detection for structural information
- MS/MS necessary for determination of arsenite in complex matrices
- Next steps include
 - Qualification of ISTDs
 - Full application of IC2-ESI-MS/MS detection
 - Faster sample preparation method using ASE® extractor
 - Additional arsenical analytes

Speciation

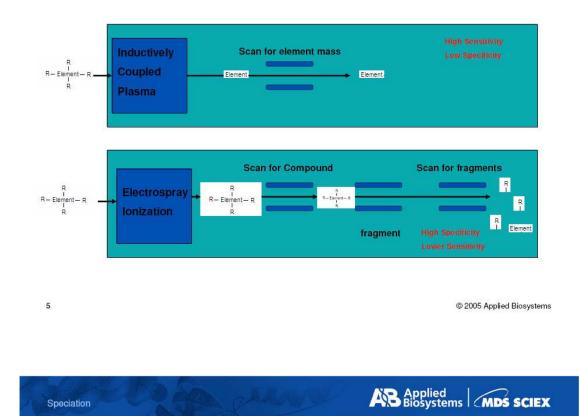

- What form is the element in
 - Amino acids, proteins, methylated species, valence states
- · Different species vary in function, nutritional value, toxicity
- Total elemental determination tells us little about fate and function
- Different types of experiment
 - <u>Discovering</u> the different forms
 - <u>Quantifying</u> the different forms

- LC-MS/MS is an alternative technique that gives A LOT more information on structure
 - Its less sensitive than ICP-MS but samples can easily be preconcentrated. It is probably worth the hassle given the information that can be gained.
- There is a case for both techniques, but in this presentation we will concentrate on the benefits of LC-MS/MS...

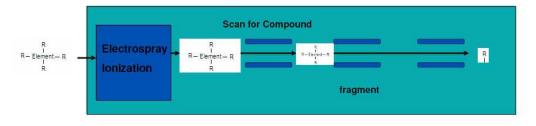

Different MS Methods

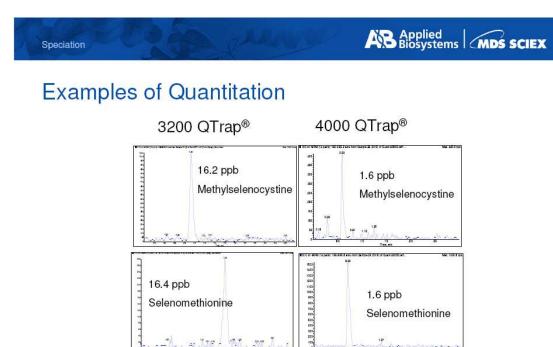

Quantitation of Known Species

Multiple Reaction Monitoring

Scan for diagnostic fragment - very high specificity

- as little as 5ms per transition
- Up to 300 transitions

Quantitation

- Highly specific transitions
 - Signal is obtained for only species of interest other species do not show up in that MRM channel
 - Multiple transitions are used to quantify many species
- In this case we are working with KNOWN species, as would be the case with ICP-MS analysis

© 2005 Applied Biosystems

Can we combine scans?

- We have discussed various scan types available on a single instrument.
- In many environmental cases we need to know for certain that a specific species is present and that the quantified species actually is that species.
- Some strategies involve multiple MRM per analyte and analyte ratio. We can also use a full scan MS-MS spectra for each compound.
- Also note that you can still do standard addition and retention time matching, as in ICP-MS, but here we have much greater opportunities.

Conclusion

- ICP-MS has excellent sensitivity, but poor selectivity for speciation
- MS/MS has excellent selectivity, but lower sensitivity than ICP-MS
- Both instruments form part of a strong speciation strategy

ROUTINE ARSENIC SPECIATION ANALYSIS BY IC-ICP-MS? ARE WE THERE YET?

Gerads, Russell and Gürleyük, Hakan; Applied Speciation and Consulting, LLC

Currently, speciation data are usually accepted only by some regulators since there seems to be no set laws or regulations on this matter. The lack of species-specific regulations may be attributed to the belief that there are no analytical methods that can reliably measure the analytes of interest at the regulatory levels. On the other hand, Method 1632a which uses hydride generation - cryo trapping - gas chromatography -atomic absorption spectrometry has been around for a long time but it is not as widely utilized since there are only a few commercial laboratories that provide this service. This operationally-defined method is known to cause false positives due to the presence of thio-arsenic species that may be present in anoxic conditions. In addition, high concentrations of iron in the sample may cause loss of arsenic during the hydride generation reaction since the borohydride reagent is preserved in alkaline conditions. If the analyst does not have a good understanding of this type of analysis and unless appropriate OA/OC protocols are followed, negatively biased results are commonly reported. Coupling Liquid Chromatography or Ion Chromatography to Inductively Coupled Plasma Mass Spectrometry (IC-ICP-MS) has been applied for the determination arsenic speciation in a variety of matrices in the last 20 years. Unfortunately, there are no EPA methods that utilize this technique and there are only two commercial laboratories that provide this analytical service. This analytical method has significant advantages over the old hydride generation method but it is not recognized by EPA and some regulatory entities. The application of IC-ICP-MS is limited to only a handful progressive companies who understand the benefits and limitations of both methods

This presentation will include a detailed comparison of analytical techniques for arsenic speciation analysis and will provide performance data for IC-ICP-MS in a variety of matrices including, wastewaters, ground waters, soils, and tissues.

Routine Arsenic Speciation Analysis by IC-ICP-MS?

Are We There Yet?

Hakan Gürleyük (hakan@appliedspeciation.com) Russell Gerads

info@appliedspeciation.com www.appliedspeciation.com

Speciation: The Hottest Topic!

- SPECIATION ANALYSIS: Separation and quantification of different oxidation states or chemical forms of a particular element.
- Interest increased exponentially in the last decade.
- Different forms can have totally different properties.
- Essential for predicting and modeling fate, risk, and effects
- A MUST HAVE for designing custom tailored treatment strategies.
- Critical for toxicology, bioavailability, and bioaccumulation.
- FINALLY, species specific regulation.

Why Doesn't Everyone Do it?

- Rarely required under current legislation in US
- Very few (promulgated) methods are available for speciation
- Although speciation can save time and money with respect to remediation and risk assessment, it is more expensive than routine analyses
- Speciation requires experienced personnel who understand proper sampling and analytical protocols
- Still not enough interest = Low ROI

APPLIED SPECIATION AND CONSULTING, LLC

Most Common Methods for As Speciation Analysis

- Selective Hydride Generation (HG-CT-GC-AAS)
- Chromatography Coupled to ICP-MS
 - Ion exchange
 - Ion Pair
- Voltammetry (not discussed)
- Other (not discussed)
 - Fluorometry
 - XANES

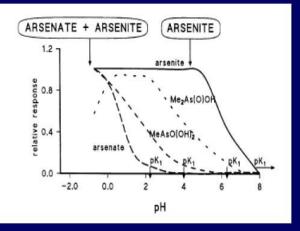

Selective Hydride Generation

	pK _{a1}		- •••
As(III) 13.4		9.2	12.1
As(V)	2.2	7.0	11.5
MMAA	3.6	8.2	-
DMAA	6.2		.
	13.4 As(V) MMAA	As(III) 13.4 As(V) 2.2 MMAA 3.6	As(III) 9.2 13.4 9.2 MMAA 3.6 8.2

APPLIED SPECIATION AND CONSULTING, LLC

Selective Hydride Generation

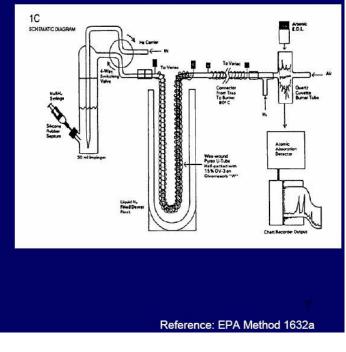

- As(III) can be determined at high pH (> 6)
- Adding a reductant to the sample, and reanalyzing As(III)+As(V) can be determined at the same pH.
- At high pH the efficiency of HG is lower.
- AFS or AAS is the most common detector
- Detection limits could be 1-5 ppb for AAS and 0.05 ppb for AFS

HG-CT-GC-AAS

- The arsines are collected on a GC column placed in a LN₂ dewar.
 - bp: -55 °C (AsH₃), 2 °C (MeAsH₂) and 36 °C (Me₂AsH)
- After collection, the Column is removed from the dewar and heated to thermally desorb and separate the arsines.
- The mobilized arsines are atomized by a H₂ flame and detected by AAS.

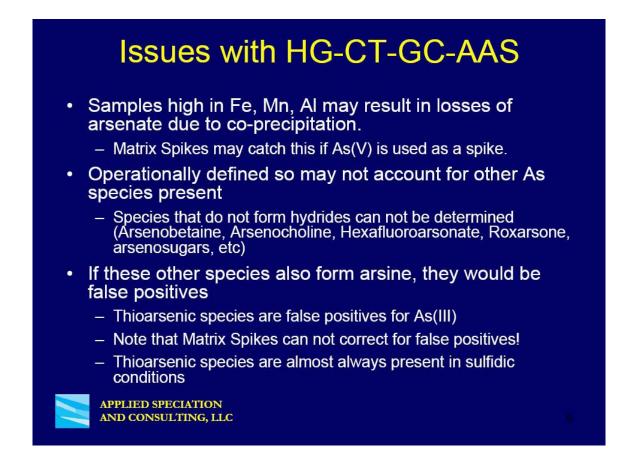

APPLIED SPECIATION AND CONSULTING, LLC

HG-CT-GC-AAS

- The sample is acidified to pH < 2 for the determination of total inorganic arsenic, DMAs(V), MMAs(V)
- Sample is buffered to pH ~5 for As(III)
- Promulgated EPA method 1632a
- Detection limits are less than 10 ppt for 15 mL sample volume. Usually limited with how clean the reagents are.
- This method can be very useful for difficult matrices as long as some type of method development is performed on the samples before aplication on the whole sample batch.

Quality Control Criteria for 1632a

	IPR (Se	ection 9.2)	OPR	Calibration	MS/MSD (Section 9.3)		
Analyte ²	s	x	(Section 97)	Verification (Section 9.5)	%R	RPD	
IA	< 25%	60-140%	50-150%	80-120%	50-150%	< 35%	
As ⁺³	< 25%	40-160%	30-170%	70-130%	30-170%	< 35%	
MMA	< 20%	70-130%	60-140%	80-120%	60-140%	< 25%	
DMA	< 30%	50-150%	40-160%	70-130%	40-160%	< 40%	

¹ Acceptance criteria based on quality control data generated during As speciation analysis for the Cook Inlet Study (1998). Details can be found in Reference 16.16.

2 IA - Inorganic arsenic (As+3 + As+5); MMA - monomethylarsonic acid; DMA - dimethylarsinic acid.

Quality Control (Variability)

Quantification by difference = compounded variability

• When the concentration of one species is much higher than the other, variability between analyses prevent accurate and precise results

<section-header><list-item><list-item><list-item><list-item><list-item><list-item><list-item>

Liquid Chromatography

- Ion-pair (IP) and ion-exchange (IE) chromatography are the most common modes of liquid chromatographic separation of mixtures of metallic and organometallic species.
- Ion exclusion chromatography is a relatively new technique and therefore there are not too many published articles on it.
- There is also some work on separation of As species by Capillary Electrophoresis (or its different versions)

APPLIED SPECIATION AND CONSULTING, LLC

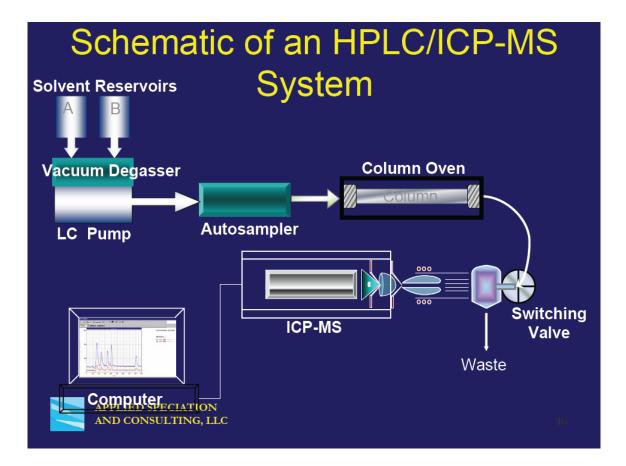

Liquid Chromatography and ICP-MS

- The most common detector for chromatographic separations is ICP-MS.
- Mature technique and almost all elements can be determined
- Sub-ppt detection limits for most elements
- More than one element can be monitored
- Polyatomic Interferences:
 - ⁴⁰Ar³⁵Cl on monoisotopic ⁷⁵As,
- Dynamic Reaction Cell instruments can eliminate interferences

Ion Exchange Chromatography – ICP-MS

- In IEC, separation is controlled by pH and ionic strength of the eluent, which competes with sample species for ion-exchange sites and elutes the sample from the column.
- Most common separation tecnique for As
- High buffer concentrations used in IE chromatography can result in nebulizer and cone clogging in ICP-MS
 - NH_4^+ salts that decompose into N_2 and H_2 are commonly used.
- Coupling of IC to the ICP-MS is very easy
- Interfering species need to be separated.
- Routinely used in our laboratory for a variety of matrices

LC/IC-ICP-MS

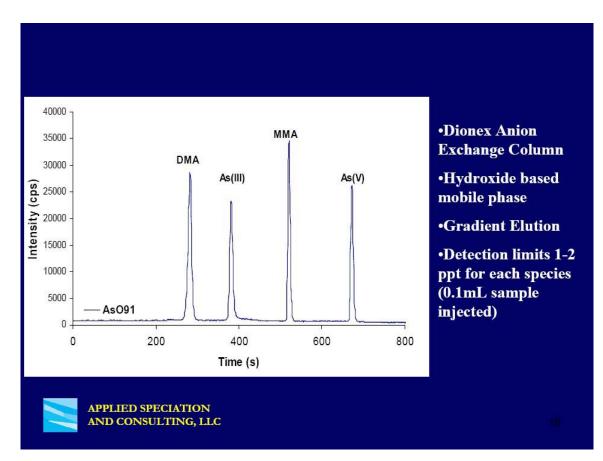

- Chromatography System
 - Dionex AGP-1 Gradient Pump
 - PKI Series 200 Pump, Autosampler, Oven and Vacuum Degasser
- ICP-MS
 - ELAN 6100DRC^{Plus}
- Software
 - ELAN 3.3 with Chromera

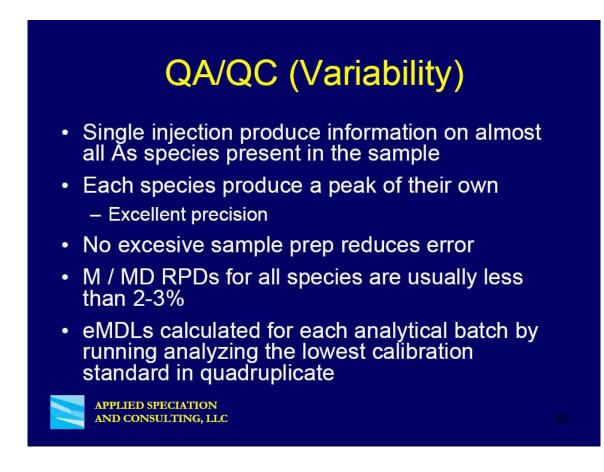

APPLIED SPECIATION AND CONSULTING, LLC

Ion Exchange Chromatography – ICP-MS Interferences?

- Chloride can cause two different types of interference
 - Spectroscopic: Formation of ArCl⁺ as a peak in the chromatogram
 - Chromatographic: High concentration of chloride can cause column overload or deteriorate separation
- Spectroscopic interference can be removed using a Dynamic Reaction Cell (DRC) instrument.
 - Use of O2 reaction gas forms AsO+ which is monitored at m/z 91
 - Extremely effective and no false positives in blood, urine, seawater, etc.
- Chromatographic interferences can be overcome by diluting the sample or using a different column

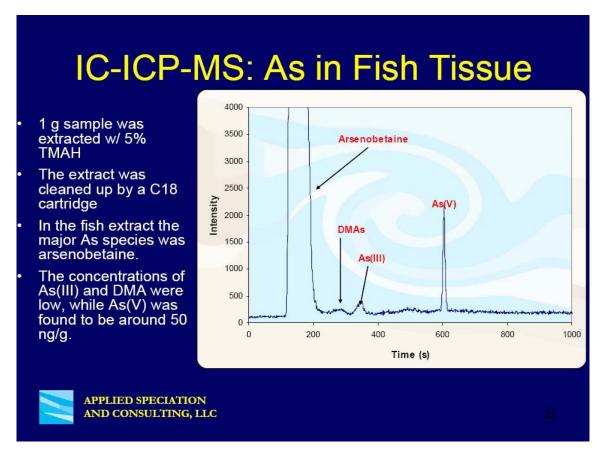

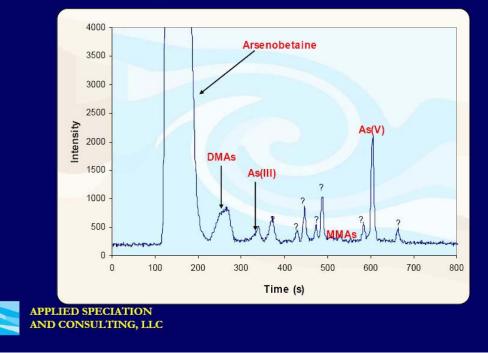

- Each As species can be spiked into sample at the same time.
- Highly reducing or oxidizing samples may cause low spike recoveries for As(III) or As(V)
 - When a low spike recovery is obtained for one inorganic As species, the other is usually high
- Compound independent calibration is possible.
 - %RSD between slopes of different As species is usually less than 5%
 - Allows accurate quantification of unknown species without any standards

APPLIED SPECIATION AND CONSULTING, LLC

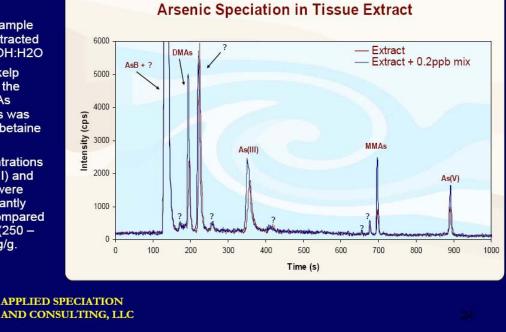

Arsenic Speciation in Fish Meal

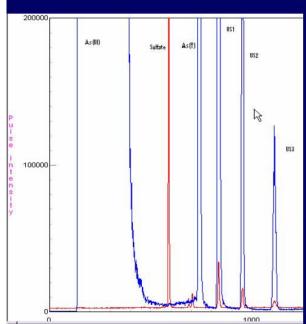

IC-ICP-MS: As in Kelp

- 0.2 g sample was extracted w/ MeOH:H2O
- In the kelp extract the major As species was arsenobetaine
- The concentrations of As(III) and As(V) were significantly high compared to fish (250 – 550) ng/g.

IC-ICP-MS: As Species in a Bacteria Growth Medium

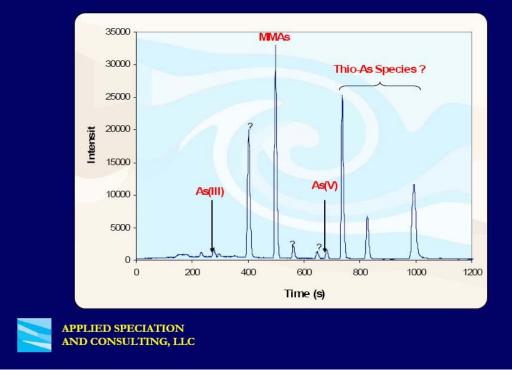

- A bacterial culture was isolated from Mono Lake, CA by scientists from USGS Menlo Park.
- It is a sulfur-reducing bacteria and also resistant to As.
- The growth medium contained high concentrations of sulfide and As(V)
- Monitored SO⁺ and As⁺ signal
- 3 Unknown peaks were present, all contained both As and S

	(S/As) US1	(S/As) US2	(S/As) US3

APPLIED AND ENVIRONMENTAL MICROBIOLOGY, May 2004, p. 2741–2747

As speciation in Mono Lake

Wastewater Sample (500X dilution)

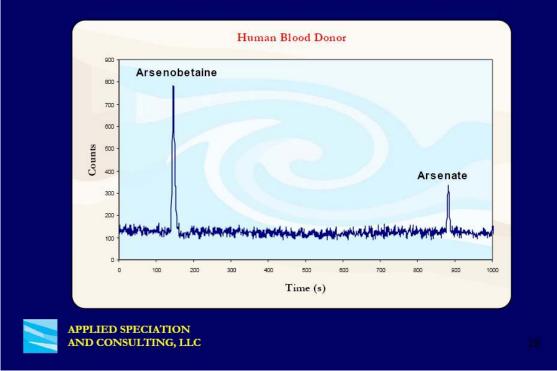

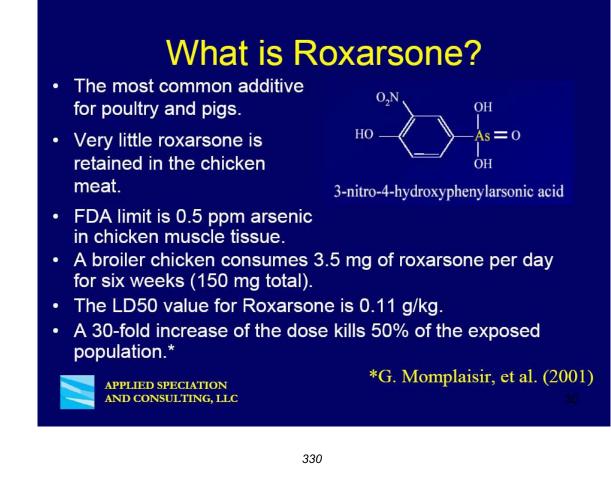

As Speciation in Blood

2

As Speciation in Blood

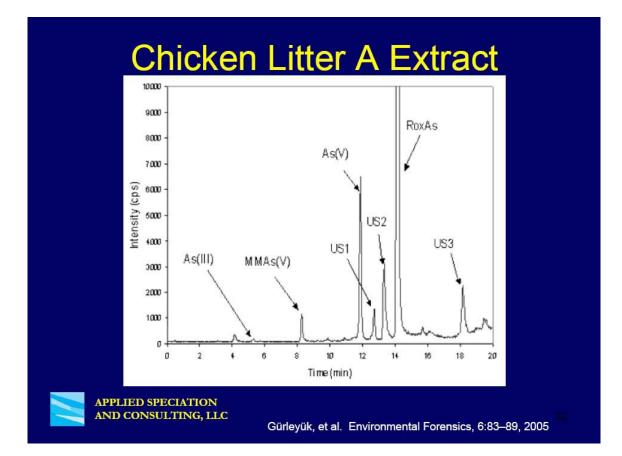

Roxarsone Contamination

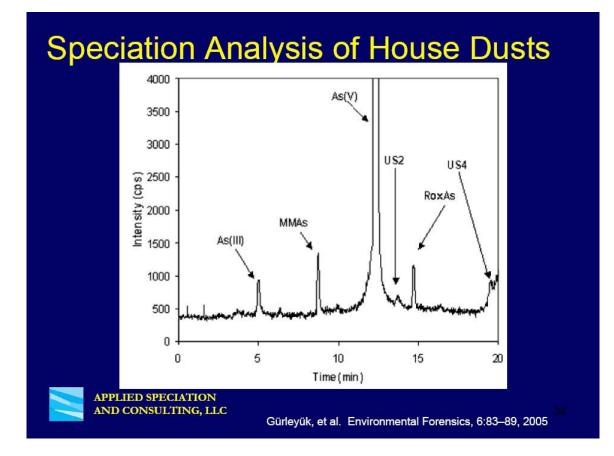

- Most of the roxarsone appears to be excreted unchanged.
- During a 6 week period, one chicken excretes approximately 150 mg of roxarsone in total.
- USDA estimates that 8.15 billion broiler chickens were produced in the United States in 1999.
- If only half of these chickens were fed feed containing roxarsone, litter that contained more than 600 tons of total arsenic was produced in 1999 alone.
- This is very significant in areas where chicken farming is concentrated.

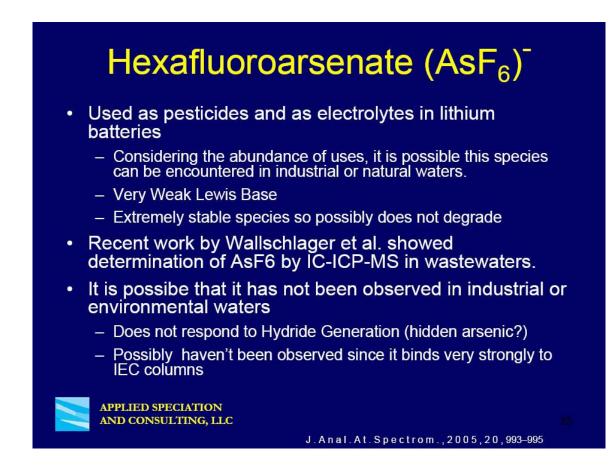

*G. Momplaisir, et al. (2001)

APPLIED SPECIATION AND CONSULTING, LLC

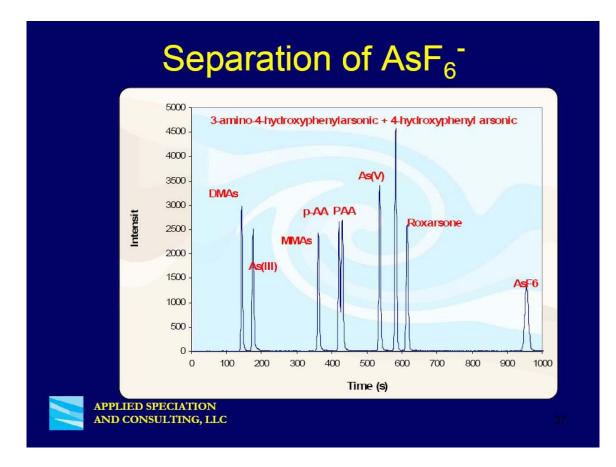

Comparison of As Speciation and Total Arsenic Data

Sample ID	As(III)	As(V)	DMAs	MMAs	Sum of Species	Missing As (%)	Total As
Sample 1	ND (<0.080)	5.41	ND (<0.066)	ND (<0.026)	5.41	93	72.2
Sample 2	ND (<0.080)	0.323	ND (<0.066)	ND (<0.026)	0.32	77	1.38
Sample 3	0.419	ND (<0.080)	ND (<0.066)	ND (<0.026)	0.42	100	187
Sample 4	0.465	ND (<0.080)	0.509	ND (<0.026)	0.97	96	23.1
Sample 5	0.533	49.2	1.29	0.579	51.6	78	237
Sample 6	0.384	22.0	1.28	0.860	24.5	73	90.8
Sample 7	ND (<0.080)	20.9	1.45	1.41	23.8	87	180
Sample 8	ND (<0.080)	2.00	2.19	ND (<0.026)	4.20	97	120
Sample 9	ND (<0.080)	1.13	1.67	ND (<0.026)	2.80	97	86.8

All results are reported in □g/L

- We have had a few cases where the sum of all As species did not match the concentration of total As in the samples
- After a quick screening, we have found that AsF6 was present in the samples

APPLIED SPECIATION AND CONSULTING, LLC

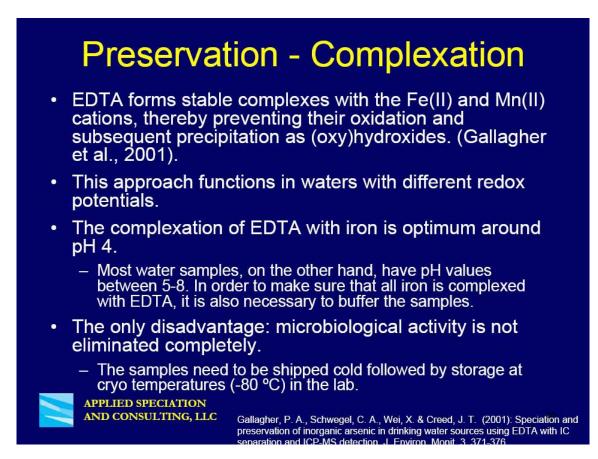

Preservation of Arsenic Speciation Even the most sophisticated analytical methods for speciation are useless if it cannot be assured that the species distribution in the sample remains unchanged between collection and analysis. Ideally, speciation should be done in the field immediately • after sample collection A number of factors, including temperature, pH, light, dissolved oxygen, container material, microbiological activity, or other water constituents, have previously been identified as potentially-detrimental to the stability of As species in waters. Every site and sample is different so there is no universal method. The best preservation technique should be selected after reviewing the site characteristics APPLIED SPECIATION

AND CONSULTING, LLC

Preservation - HCI

- At low pH, the oxidation kinetics of the thermodynamically instable As(III) are slowed down to an extent.
- Acidification prevents the oxidation and/or precipitation of major matrix constituents, especially Fe(II), which would subsequently precipitate as Fe(III)-(oxy)hydroxides.
 - Arsenate binds strongly to such minerals, and would therefore coprecipitate with them.
- Hydrochloric acid itself is redox-neutral, but free chlorine, a very potent oxidizer, is sometimes present or may form during storage which may induce oxidation of arsenic and iron.
- In addition, it has been shown that As(III) can form AsCl₃ in the presence of excess chloride (Mester and Sturgeon, 2001). AsCl₃ is also a volatile species which can be lost in the sample headspace before analysis.

APPLIED SPECIATION AND CONSULTING, LLC

Preservation – Cryofreezing

- One of the best preservation techniques for arsenic speciation is flash cryo-freezing in the field.
- Storage temperature can affect the stability of As species through a number of different mechanisms. First, reduced temperature slows down all biotic and abiotic reactions, including the diffusion necessary for aqueous phase reactions.
 - As a rule of thumb, for every ten degree temperature difference, reaction rates change by a power of two,
 - Compared to RT conditions, frozen storage on dry ice should reduce those reactions by a factor of 64 and freezing with liquid nitrogen at -196 °C should reduce the reactions by many orders of magnitude.
- The major advantage of flash cryo-freezing is that no chemicals are added to the sample which does not change the native sample composition and eliminates the the fear of contaminating the sample.
- The major disadvantage of this technique is its practical limitations for routine use.
 - Field sampling personnel may be unable to use it due to a wide variety of reasons, including occupational safety concerns or inaccessibility of liquid N2 in the field.
 APPLIED SPECIATION

- Field Spikes • Applied Speciatio also utilizes field spikes to confirm preservation of species information. – A stock solution of As standards is added to specific samples
 - These samples are analyzed to determine if any oxidation or co-precipitation reactions occur during sampling and shipping

APPLIED SPECIATION AND CONSULTING, LLC

AND CONSULTING, LLC

42

- HG-CT-GC-AAS provides limited amount of information
 - May not produce quality data if applied to every single matrix without prior method development/improvement
 - Projects that require 1632 should consider IC-ICP-MS as a QA/QC check for this method
- IC-ICP-MS has been applied for As speciation in many different matrices successfully at Applied Speciation
- ASC does not have a universal method for As speciation
 - Different methods for different matrices
- Experience is very important
 - While setting up an IC-ICP-MS system is very easy, the most important things to consider is:
 - Knowledgeable project managers
 - · Experienced analysts who are familiar with both IC/LC and ICP-MS systems
 - Analysts that can interpret and report the data

DIRECT INJECTION OF WATER SAMPLES TO ANALYZE PESTICIDES AT CONCENTRATION OF 0.1µG/L USING LC/MS/MS

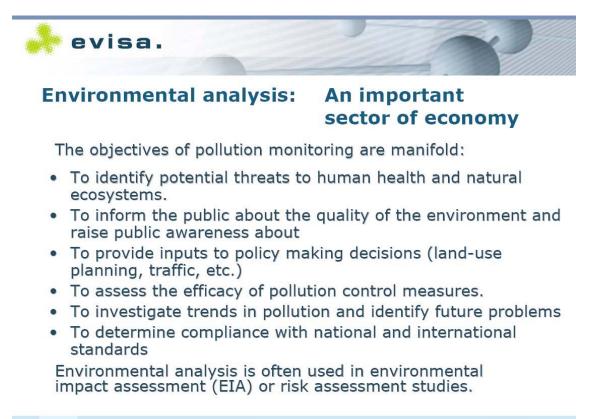

Besa, Axel – Applied Biosystems; Dahlmann, Jens – Applied Biosystems; El Aribi, Houssain – MDS Sciex; Ellis, Robert – MDS Sciex; Schreiber, André – MDS Sciex

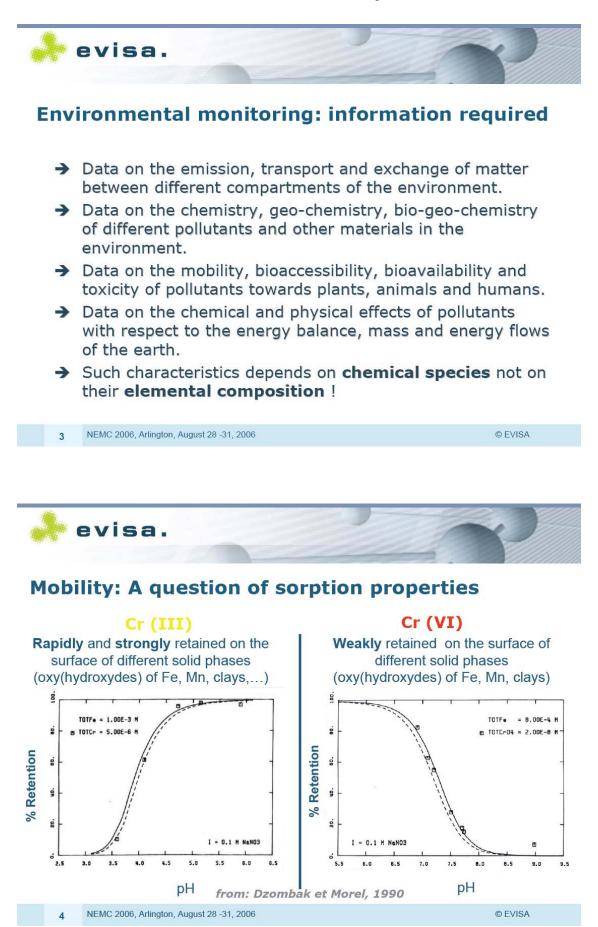

Currently more than 800 pesticides are used worldwide. Many pesticides are difficult or not to analyze by GC/MS but can be identified and quantified by multi-residue methods using Liquid Chromatography combined with tandem Mass Spectrometry (LC/MS/MS). Multiple Reaction Monitoring (MRM) is the preferred scan type for this kind of application. However, a single MRM transition per pesticide is not enough to validate the presence of a pesticide without any doubt. Typically, a second transition (qualifier) or an MS/MS spectrum is used to confirm analytical results. Depending on the number of compounds to be analyzed confirmation should be performed using a qualifier transition using a triple quadrupole MS or by automatically acquired Enhanced Product Ion spectra using a Hybrid Triple Quadrupole Linear Ion Trap MS, such as a QTRAP[®] system.

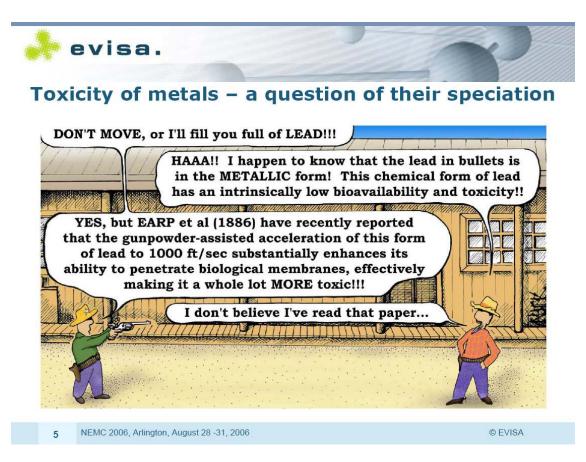

Quantitation and confirmation have to be performed reliable at concentrations of legal action level. The maximum residue level of pesticides is set to $0.1 \mu g/L$ in many countries.

This presentation will focus on recently developed LC/MS/MS methods and software tools to assist method development. Examples of analyzing pesticides of different compounds classes, such as triazines, phenyl ureas, phenoxycarboxylic acids, Glyphosate and metabolites in water samples will be presented. All methods allow quantitation and confirmation at a level of 0.1µg/L without time consuming sample preparation. Reporting of analytical data was done using an automated reporting tool.

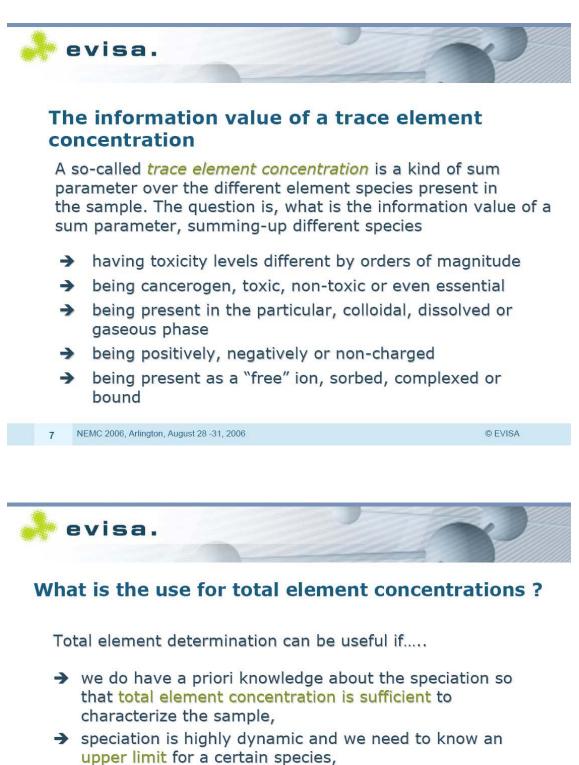

Toxicity and speciation

The toxicity of often called "toxic trace elements" depends on their speciation and concentration not only in a **quantitative** way but also in a **qualitative** way. Some examples:

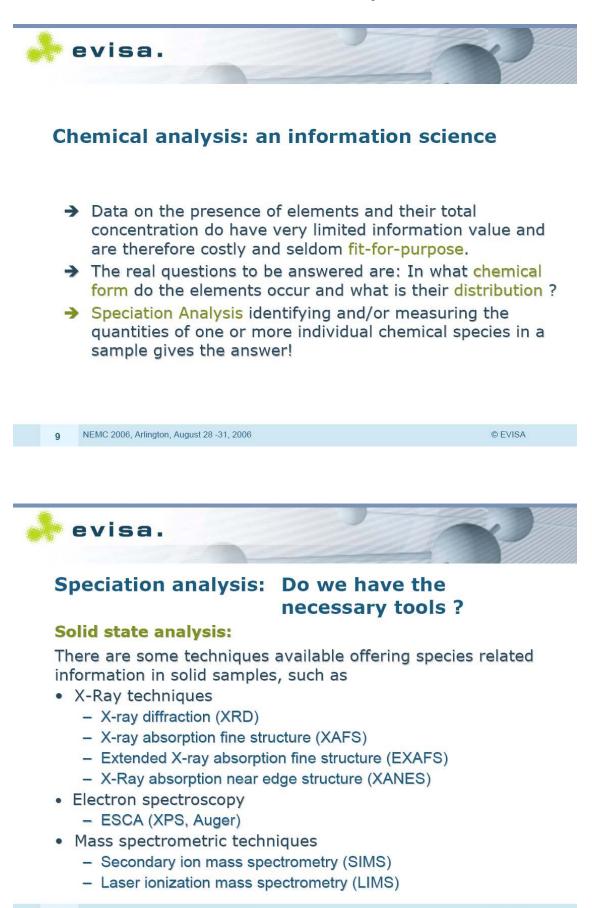

Chromium:	Cr(III) is considered to be essential while Cr(VI) is carcinogen	
Arsenic:	Inorganic As(III) compounds are carcinoger while Arsenobetaine is essential non-toxic	n
Tin:	Inorganic tin compounds are nutrients for animals but tributyltin (TBT) is an endocrine disruptor	9

NEMC 2006, Arlington, August 28 -31, 2006

6

- → as a quality check of our speciation analysis (mass balance),
- ➔ we cannot get more specific information,
- → rules and legislation force us to present such data

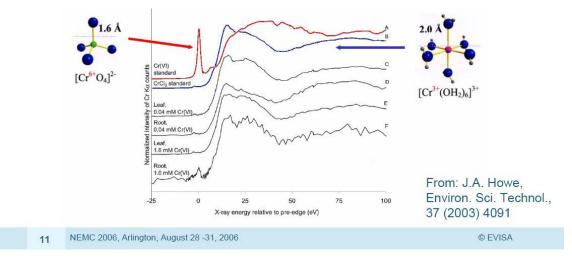

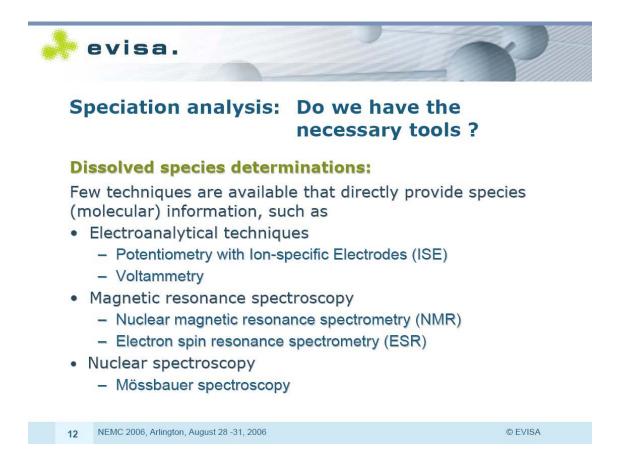

¹⁰ NEMC 2006, Arlington, August 28 -31, 2006

XANES: Direct solid state speciation

The near edge structure of an X-ray absorption spectrum is sensitive to the coordination and oxidation state of the absorbing atom. For example, the XANES region of $Cr^{3+}(aq)$ and $[Cr^{6+}O_4]^{2-}(aq)$ are very different.

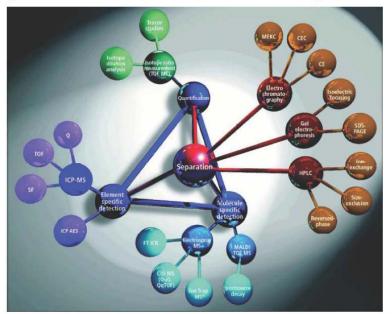

Speciation analysis: Do we have the necessary tools ?

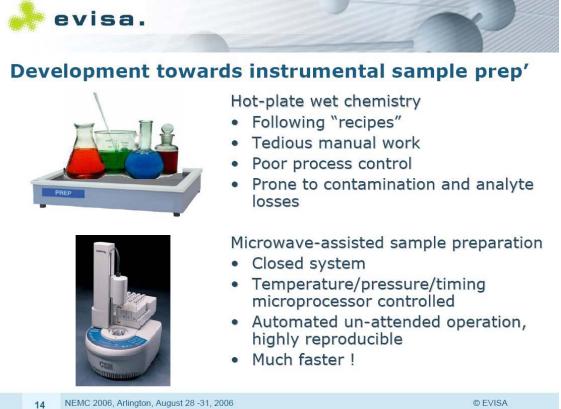

We do have a fully developped tool-box for the

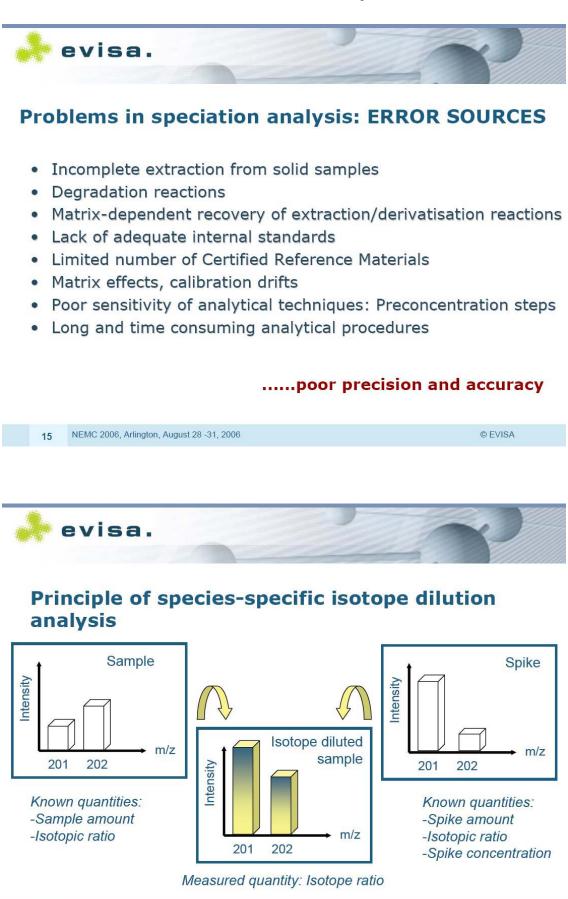

- separation
- detection
- identification

 quantification of elemental species.

"Real world" environmental and industrial speciation issues

Drinking water:

- Enhanced characterisation of fresh water with respect to requirements for water treatment (Fe(II)/Fe(III), As(III/As(V))
- Influence of pH, different water sources and disinfection products on remobilisation of deposited minerals from distribution system (e.g. As, Pb)
- Process control and elimination of toxic contaminants from drinking water (As(III)/As(V), Bromate)

Arsenic speciation: A necessary information

Data on arsenic speciation is necessary for:

- → Tracing the source of contamination of drinking water (geological, pesticides, wood preservation, chicken manure)
- → Understanding the bio-geochemistry behind the arsenic cycling
- → Designing remediation strategies
- → Controlling water treatment plants
- → Evaluating of the Health Risk's for the consumers

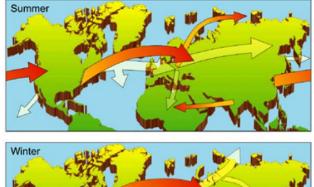

Mercury as a global pollutant

The US sends it to Europe; they send it to Asia. But what happens when China starts sending more our way?

Or....

"Everyone is worrying about everybody else"

Mercury as a global pollutant

Speciation greatly influences the transport within and between environmental compartments (e.g atmosphere, oceans), e.g. Hg speciation is a determining factor for how far from the source mercury emitted to air is transported:

- Mercury adsorbed on particles and ionic mercury compounds will fall on land and water mainly in the vicinity of the sources (local to regional distances)
- Elemental mercury vapour is transported on a hemispherical/global scale making mercury emissions a global concern.

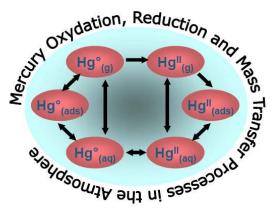

Mercury species and transformation in the atmosphere

The atmospheric chemistry of mercury involves several interactions:

- → Gas phase reactions;
- Aqueous phase reactions (in cloud and fog droplets and deliquesced aerosol particles);
- Partitioning of elemental and oxidized mercury species between the gas and solid phases;
- Partitioning between the gas and aqueous phases; and also
- Partitioning between the solid and aqueous phases in the case of insoluble particulate matter scavenged by fog or cloud droplets.

Mercury species and transformation in aquatic environments

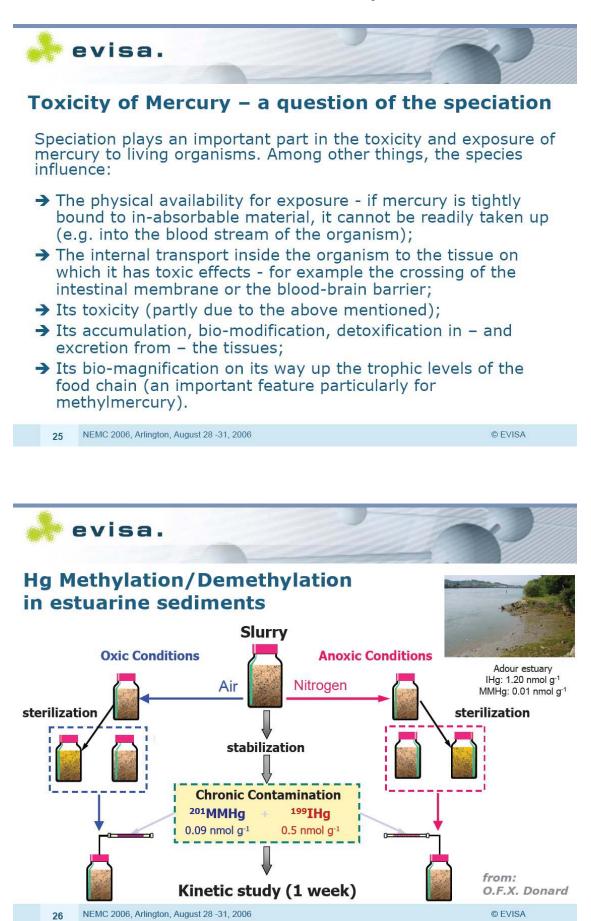

Methylmercury can be formed in the environment by microbial metabolism (biotic processes) such as by certain bacteria and by chemical processes that do not involve living organisms (abiotic processes). The formation of methylmercury in aquatic systems is influenced by a wide variety of environmental factors:

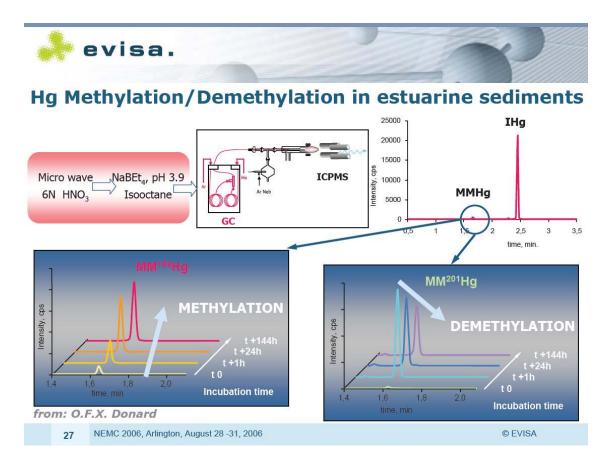

- Microbial activity (sulfur concentration)
- Mercury availability (temperature, pH, redox potential, inorganic and organic complexing agents)

Dynamic interactions between the various mercury species in ocean waters (based on Mason and Fitzgerald, 1996). Hg(0) = elemental mercury, DMHg = dimethylmercury,

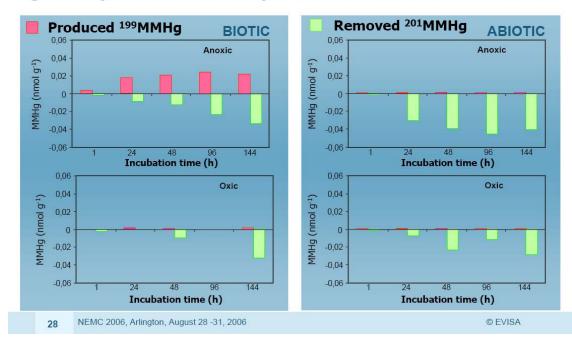

MMHg = (mono)methylmercury.

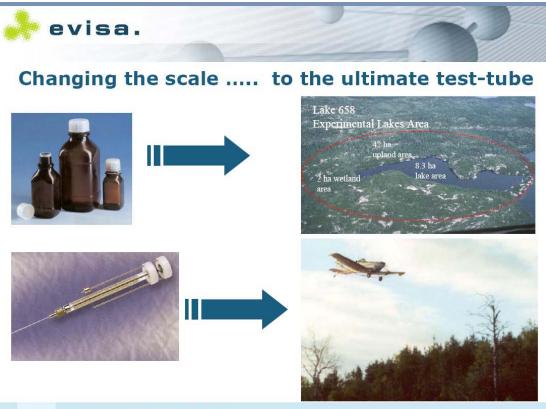

Hg Methylation/Demethylation in estuarine sediments

Managing Uncertainty

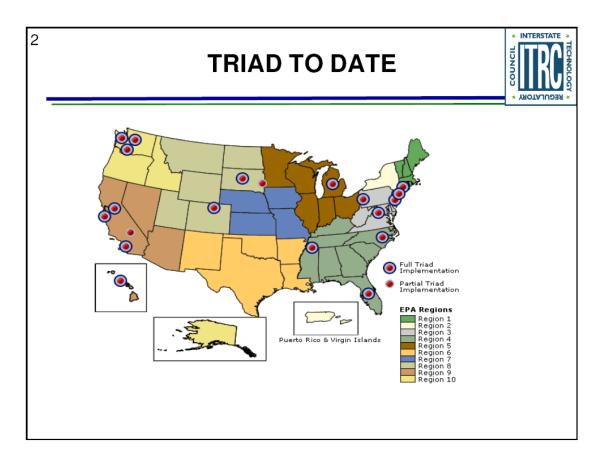

TRIAD: WHY ISN'T IT USED MORE?

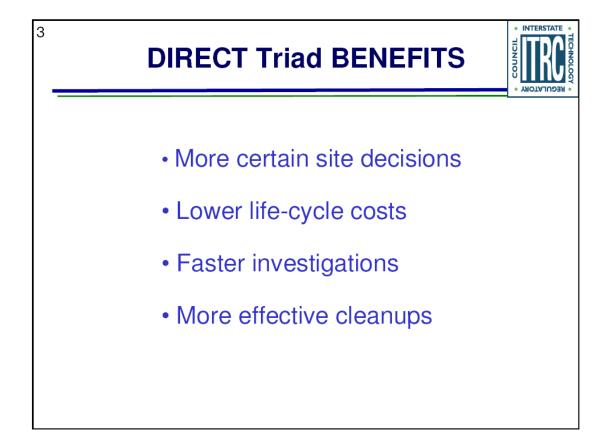

Nagourney, Stuart J.; New Jersey Department of Environmental Protection Office of Quality Assurance

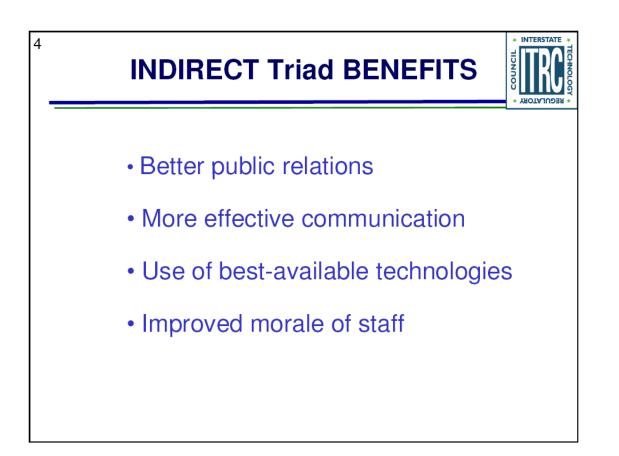

With improved measurement certainty and documented reductions in project time and cost, Triad should be the de-factor strategy for many if not most remedial projects throughout the United States. The reality is that most State and Federal agencies either do not utilize Triad at all or employ it only sporadically.

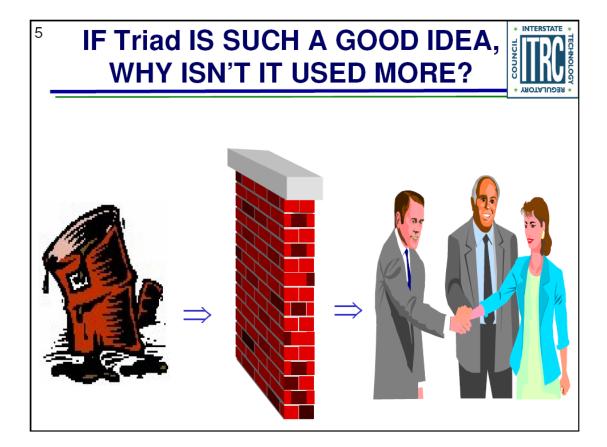

With several years of support by State remediation program management and involvement in Federal national implementation efforts, the New Jersey Department of Environmental Protection has been at the forefront in promoting the use of Triad. This paper will discuss a variety of reasons why Triad is not used more and more widely and offer suggestions to make it more broadly applicable.

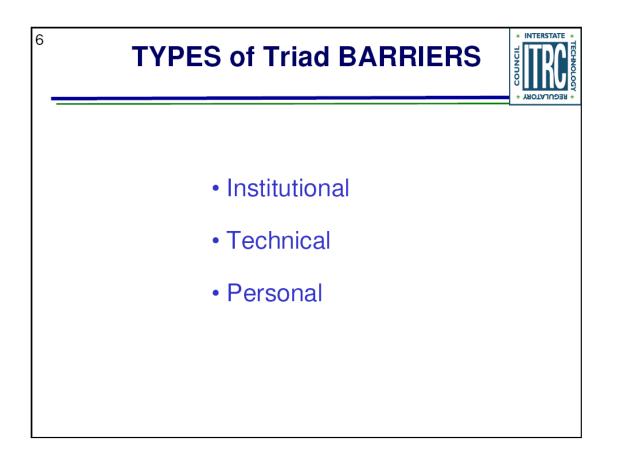

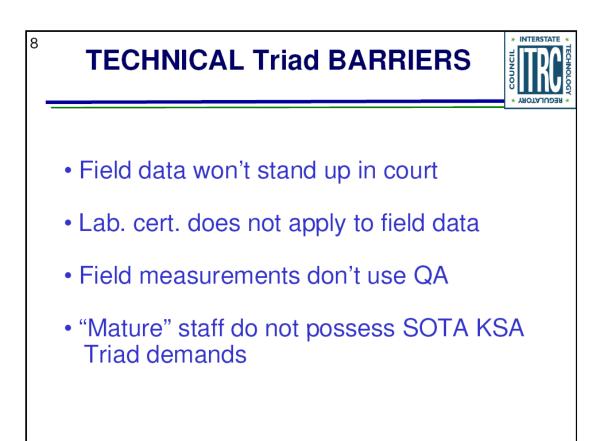

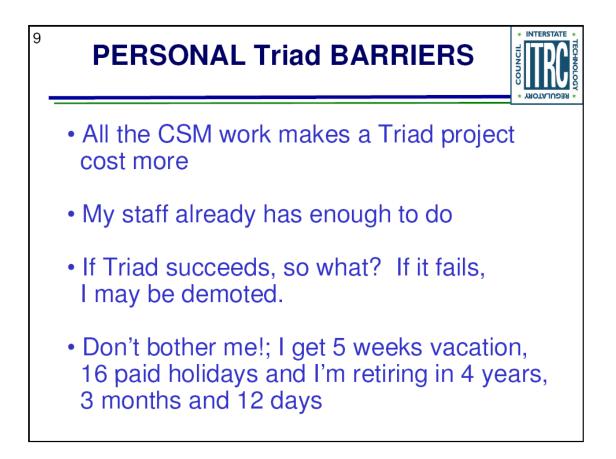

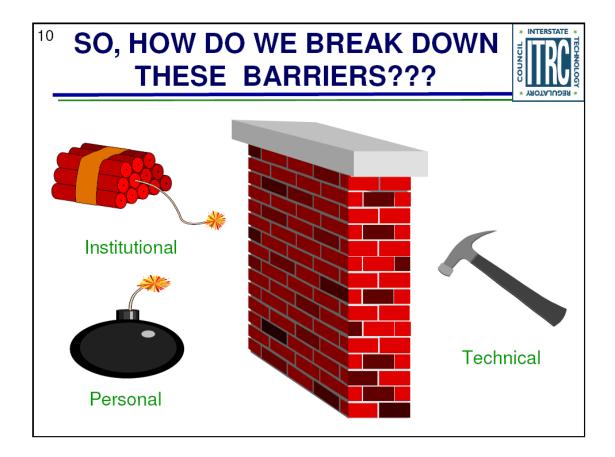

BREAKING INSTITUTIONAL Triad BARRIERS

11

12

- Machiavelli designed bureaucracies to be slow to change
 But ones that survive do change
- Triad can't replace our current remedial policies
 Triad's just a case-selective supplement
- Mid-level mangers make it happen; most fear failure much more than they are excited by prospects for success
 You are not alone and are not breaking new ground
- Triad is just another fad or re-cycled ideas
 So it really isn't new; it does not make it a bad idea
- What will my new boss think about Triad?
 - If Triad succeeds, they won't care

BREAKING TECHNICAL Triad BARRIERS

- Field data won't stand up in court

 See Daubert & Frye; the "Supremes" disagree
- Only lab. cert. data is any good; field data NG
 NJDEP and NELAC strongly disagree
- Field measurements don't use QA
 - You may need to repeat 2nd year of college chem.; <u>any</u> analytical measurement has appropriate QA
- "Mature" staff do not possess SOTA KSA Triad demands
 - Find a Triad champion in your agency
 - There is nothing in Triad that a good Jr.
 - scientist/engineer can't handle

BREAKING PERSONAL Triad BARRIERS

13

14

- All the CSM up-front work makes a Triad project cost more

 Like brain surgery; the 1st few times are the hardest
- My staff already has enough to do

 But with Triad, you might actually finish some cases
- If Triad succeeds, so what? If it fails, I may be demoted
 It has not happened yet
- Don't bother me!; I get 5 weeks vacation, 16 paid holidays and I'm retiring in 4 years, 3 months and 12 days
 You can learn "Triad 101" in a day or 2; then, turn it over to the "Triad Champion" and coast your way to Florida

MY 10 STEP PROGRAM TO Triad SUCCESS

- 1. Learn something about Triad
- 2. Survey your internal resources; pick a few of your best staff to be involved
- 3. Get Triad training from EPA & USGS
- 4. Develop an implementation plan
- 5. Engage your upper management
- 6. Start small with a "low-hanging fruit"
- 7. Get FAMs certified so field data is OK
- 8. Feign interest in outcomes
- 9. Document project outcomes, both technical and financial
- 10.Expand Triad application very slowly

¹⁵ WHAT ARE FUTURE MARKERS FOR Triad SUCCESS

- More states get involved
- Brownsfields projects predominate
- Triad becomes a State-driven initiative, and not viewed as an EPA idea
- Field data become as acceptable as data from fixed-based labs.
- Triad is no longer a "new" concept

Estimation of Uncertainty Based on QC Data: Nested Hierarchical Approach

William S. Ingersoll

NAVSEA Programs Field Office (SEA 04XQ LABS)

ABSTRACT

The concept of analytical measurement uncertainty is widely recognized in analytical chemistry. Uncertainty is usually estimated from replicate preparation and testing of a sample resulting in a range of measurements. This variability of measurements represents the analytical measurement uncertainty. However, routine replicate preparation and testing of environmental samples is not practical. Most environmental samples are prepared and tested only once. For this reason, quantification of the analytical measurement uncertainty is usually not performed in environmental testing laboratories.

An approach for estimating uncertainty was developed based on quality control data. Conceptually, the components of uncertainty can be modeled as being nested within the quality control samples and standards in a hierarchical structure. The data from routine quality control samples and standards are used to "back out" the uncertainty associated with the components of the analytical process and then component uncertainties are combined. The combined uncertainty can then be expanded to a particular level of statistical confidence.

INTRODUCTION

The International Organization of Standardization (ISO) and the International Electrotechnical Commission (IEC) have developed the ISO/IEC 17025 standard, "General Requirements for the Competence of Testing and Calibration Laboratories," December 1999. This standard is used by accrediting bodies worldwide when assessing laboratory capability to generate quality data. In addition, this standard is being integrated into the NELAC Quality Systems Standard. According to ISO/IEC 17025, a laboratory "shall have and shall apply procedures for estimating uncertainty of measurement." (Section 5.4.6.2) As a consequence, environmental laboratories will be required to demonstrate the quality of their analytical measurement data. Documentation of analytical measurement uncertainty is a valuable demonstration of data quality.

The estimation of analytical measurement uncertainty is formalized in the "U.S. Guide to the Expression of Uncertainty in Measurement," (US GUM), published by American National Standards Institute (ANSI) in 1997. The US GUM is the ANSI adoption of the ISO "Guide to the Expression of Uncertainty in Measurement," (GUM), published in 1993, and it establishes general rules to evaluate and express uncertainty for quantitative analytical measurements. This internationally recognized approach requires evaluating, expressing, and reporting the uncertainty associated with analytical measurement results. The US GUM approach establishes a uniform presentation of data that promotes data comparability and data quality evaluation in which the estimated uncertainty is the confidence interval centered on the analytical measurement and provides a realistic level of confidence when making a decision using the result.

Most current environmental programs do not define the process for determining and reporting analytical measurement uncertainty. The overall analytical measurement uncertainty includes both field sampling and laboratory activities. Therefore the definition and determination of measurement uncertainty required by the decision-maker is not exclusively a laboratorygenerated quantity. The laboratory provides the data for calculating the uncertainty associated with laboratory activities, but the decision-maker must also incorporate the uncertainty associated with field activities into the uncertainty equation for environmental decisions. The nested approach described in this paper provides a comprehensive procedure for reporting the laboratory contribution to the variability in the field sampling and laboratory testing data used for environmental regulatory programs.

ESTIMATING AND EXPRESSING UNCERTAINTY

The general rules for evaluating and expressing analytical measurement uncertainty are simple in concept. According to the US GUM, the general rules are not "detailed, technology-specific instruction." (US GUM, Section 1.4)

The steps for estimating uncertainty are incorporated into the following conceptual algorithm:

- Specify the analyte of interest that is to be quantified
- Identify the sources of analytical measurement uncertainty
- Quantify the components of analytical measurement uncertainty
- Calculate the combined and expanded analytical measurement uncertainty

The first step is to state what is to be quantified (the analyte of interest). For environmental analytical measurements, the analytes of interest include inorganic, organic, and radioactive parameters. In addition, a specified sequence of activities is required to collect, prepare, and quantify the analyte of interest. A summary of the preparation and testing method with statements concerning the activities required to analyze the analyte of interest in the sample should be included in the quantification statements (laboratory report). Method performance in real-world matrices should also be quantified.

The second step is to identify the sources of analytical measurement variability or uncertainty. The sources of uncertainty can be partitioned into the following general components:

- Sampling site media
- Sampling strategy
- Sample collection
- Sample prep
- Sample matrix
- Test measure

Each component contributes or "causes" the uncertainty "effect" on the measurement. This is represented in the following figure (Figure 1):

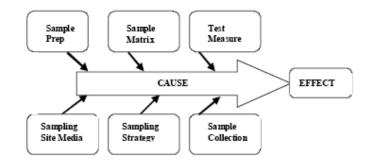

Figure 1: "Cause-and-Effect" Diagram

Environmental laboratories control subsampling, sample preparation, and sample testing, and must estimate the uncertainties associated with these components. The sources of uncertainty include sample compositional and distributional heterogeneity, chemical digestion or extraction, instrument response, calibration and standardization, and sample matrix interference.

The third step is to quantify the components of analytical measurement uncertainty. A frequent approach to evaluating and expressing uncertainty of a measurement is the use of the statistical concept of the confidence interval. The confidence interval is the range of results that reasonably captures the analyte concentration with a specified probability. When the confidence interval is constructed by the statistical analysis of replicate results, the approach is a type A evaluation of standard uncertainty (US GUM, Section 4.2). When the confidence interval is not constructed by statistical analysis of replicate results, the approach is a type B evaluation of standard uncertainty (US GUM, Section 4.2).

The fourth step is to combine the individual uncertainties and then apply a "coverage factor" which is chosen on the basis of the desired level of confidence to be associated with the interval around the measurement. Typical coverage factors are 2 and 3, corresponding to intervals with levels of confidence of approximately 95% and 99%, respectively.

Less rigorous approaches such as the use of laboratory control samples (LCS) quality control limits or the use of proficiency testing (PT) study acceptance limits misrepresent the uncertainty associated with analytical measurement of real-world environmental samples. The LCS approach does not capture matrix interferences on subsampling, sample preparation, and sample testing associated with real-world environmental samples. The PT approach uses the pooled results of laboratories that participate in the studies and does not represent the analytical measurement uncertainty associated with a particular laboratory.

THE NESTED APPROACH

Environmental samples are routinely prepared and tested only once per sample. Thus any rigorous statistical determination of uncertainty is not possible. However, readily available laboratory quality control standard and sample replicate data are available, and these data can be used to estimate the analytical measurement uncertainty for single test results. Using these quality control limits, a mathematical model can be constructed to systematically "back-out"

component uncertainties. The mathematical model is based on summing in quadrature or square root sum of the squares equation.

Quality control standards and samples included the following:

- Instrument standardization (calibration) standard (ICAL)
- Instrument independent calibration verification (ICV)
- Instrument continuing calibration verification (CCV)
- Laboratory control sample (LCS)
- Matrix spike sample (MS)
- Duplicate matrix spike sample (MSD) or duplicate sample (Dup)

The relative standard deviation for each quality control standard or sample is calculated by dividing the acceptable deviation of the quality control standard or sample by 3 (assuming a 3σ control limit). For example, if the quality control limits are 95-105% recovery for the ICAL, then the acceptable relative deviation from the reference value is \pm 5%. This 5% is divided by 3 for a standard deviation of 1.67%. The other standard deviations are calculated in a similar fashion. The following table (Table 1) presents example control limits and relative standard deviations for the quality control standards and samples.

Quality Control Standard or Sample	Quality Control Limits in Percent	Percent Relative Standard Deviation in Percent
Instrument Standardization (Calibration) Standard (ICAL)	95-105	1.67
Instrument Independent Calibration Verification (ICV)	90-110	3.33
Laboratory Control Sample (LCS)	80-120	6.67
Matrix Spike Sample (MS)	70-130	10

Table 1: Example Quality Control Data

The ICAL standard variability is the result of the instrumental variability or repeatability. The ICV variability is a result of a combination of the testing variability and the spike preparation variability. The LCS variability is a result of a combination of the testing variability, the spike preparation variability, and the sample preparation variability. The MS variability is a result of a combination of the testing variability is a result of a combination of the testing variability, the spike preparation variability, subsampling variability, the spike preparation variability, the sample preparation variability, subsampling variability, and the matrix effects on sample preparation and testing variability. These individual component uncertainties can be partitioned by the "backing-out" approach. Backing-out means working backwards from the quantified relative standard uncertainties of quality control limits to estimate the relative uncertainties of the general components of the analytical measurement procedures. This procedure can be simplified by using standard computer programs such as Excel. By including matrix spike data, the nested approach can provide a comprehensive procedure for reporting the variability in the field sampling and laboratory testing data used for environmental regulatory programs.

Once the relative standard uncertainties associated with the laboratory contribution to analytical measurement uncertainty, including the contributions from subsampling, matrix interference,

sample preparation, and sample testing, have been determined, they are combined into the relative standard uncertainty for routine environmental samples. This combined relative standard uncertainty can be expanded to a specified confidence level. Thus, when reporting analytical measurement results, an estimation of uncertainty is required to fully quantify the results. For example, if the analytical measurement result is 100 μ g/L and the combined relative standard uncertainty is 9.5%, the analytical measurement is reported with a confidence interval of ± 19% of the analytical measurement at the 95% level of confidence:

Equation 1: Calculation of Uncertainty

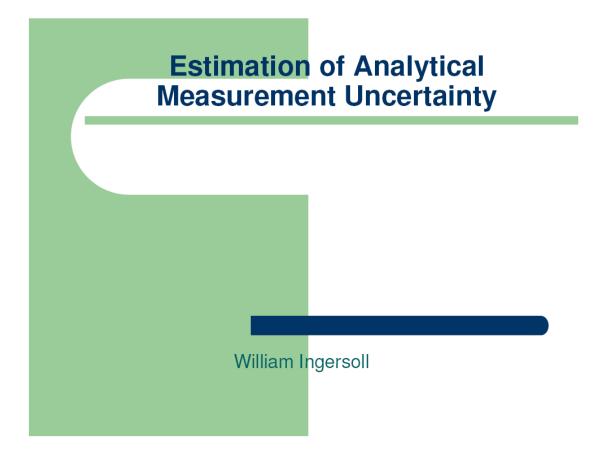

Reported Analytical Measurement = $100 \ \mu g/L \pm (100 \ \mu g/L * 0.19) = 100 \pm 19 \ \mu g/L$

CONCLUSION

The QC-based nested approach for estimating analytical measurement uncertainty is capable of capturing the matrix interferences on specific laboratory subsampling, sample preparation, and sample testing of real-world environmental samples. It was specifically designed to estimate analytical measurement uncertainty for single test results of environmental samples. The nested approach promotes a uniform expression of the environmental data that is consistent with international definitions. It is a useful tool for identifying, quantifying, and comparing components of uncertainty. Ultimately, the environmental decision-maker must evaluate the significance of these sources of uncertainty and determine the acceptability data variability from these components.

MAKING A DECISION WITH VARIABLE DATA

Moore, Marlene; Advanced Sytems, Inc.

Data usability is the report on the adequacy of data for making decisions, performed after completion of the report on the results of validation and verification. The usability step involves assessing whether the process execution and resulting data meet project quality objectives documented in the Quality Assurance Project Plan (QAPP).

A usability determination considers whether data meet project quality objectives as they relate to the decision to be made, and evaluates whether data are suitable for making the decision. All types of data (e.g., sampling, on-site analytical, off-site laboratory) are relevant to the data usability determination. The decision maker uses this information in order to make decisions with variable data.

Data usability is the last step in the data review process. Data review is the process which data are examined and evaluated to varying levels of detail and specificity by a variety of personnel who have different responsibilities within the data management process. It includes verification, validation, and usability assessment.

The project team at the start of the project defines the data usability assessment process. The items to consider for the usability assessment:

- The usability assessment must follow the verification (completeness of sampling and testing records) and validation (compliance with method and project requirements for sampling and testing). (See Table 8 from the UFP-QAPP Reference 2).
- Summarize the usability assessment process and all usability assessment procedures, including interim steps and any statistics, equations, and computer algorithms that will be used to assess data.
- Describe the documentation to be generated during the usability assessment.
- Identify the personnel (by title and organizational affiliation) responsible for performing the usability assessment. Define the qualification of the personnel to perform and review the assessment.
- Describe how usability assessment results are to be presented in order to identify trends, relationships (correlations), and anomalies.
- Describe the evaluative procedures used to assess overall measurement error associated with the project and include the data quality indicators (DQIs) or measurement quality objectives (MQOs) as defined for the project.

In the past, the only formal data review was limited to the contract laboratory program test data as defined in the EPA contract requirements for data validation (CLP). These data validation

protocols included a section for "Overall Assessment". This assessment is described as "a brief narrative in which the data reviewer expresses concerns and comments on the quality and, if possible, the usability of the data".

To develop this narrative, the data validator uses "professional judgment to determine if there is any need to qualify data which were not qualified based on the QC criteria previously discussed". However this was limited only to the laboratory data and does not address the sample collection or sampling design.

The CLP provides a series of contract specifications in the form of a statement of work that covers laboratory services purchased under specific contracts for Superfund sites. The CLP also provides guidelines for evaluating laboratory conformance to its contract specifications; however, it does not address any of the data usability requirements and therefore does not provide assurance that collected data are appropriate for their intended uses. There are many environmental programs not covered by CLP, and many aspects of environmental data collection outside its scope (e.g., the systematic planning process, sampling activities, QA oversight). The CLP does not address the assessment of the overall quality system for the project. Any deviations that affect the quality of the data must be presented in the data usability report.

A data usability assessment requires a review of the QAPP and sufficient communication with the data user(s) to develop a clear understanding of the intended use and desired quality of the data. It requires the validator to obtain a more complete record of the sampling and laboratory's activities, including logs for sample collection, handling, preparation, calibration, and instrument performance; instrument printouts; and raw data. The extent to which data validators have access to these types of information depends on the project management team.

Data usability is a detailed investigation of particular data records that need special interpretation or review. The purpose of the data usability is to answer questions about the data that arise as a result of the data user's review of the data verification and data validation report. The inputs to the data review include the planning documents, data validation report, hard-copy data package, the validated data set, and a general knowledge of the environmental problem and its history. As the information is reviewed, the data user is looking at whether the data appears to be appropriate and sufficient to support decision-making based on the original project needs. The data user may also identify errors or omissions in the data or data validation report that need to be corrected. The report should include items such as a list of the samples collected, field information about how the samples were collected, the analysis performed on the samples, and the quality of the reported data. The data reviewer should attempt to document anything out of the ordinary that is noticed about the data during their review. Examples of data validation and data suitability are presented in Table 9 (EPA/QA G-8 Reference 1).

The data usability assessment completes the data review activities used to ensure that only scientifically sound data that are of known and documented quality and meet project quality objectives (PQOs) are used in making environmental decisions. The approach used for data review of a project must be appropriate to the project requirements.

IDQTF UFP-QAPP Manual Page: 109 of 149

Process Term	Objective	Scope	Data Review Step	Output
Verification	Review to see if data required for the project are available.	– Sampling* – Analysis	I. Completeness check	Verification Report – May be checklist form – Package includes all documentation
Validation	 Assess and document the performance of the field sample collection process. Assess and document the performance of the analytical process. 	– Sampling* – Analysis	IIa. Check compliance with method, procedure, and contract requirements IIb. Compare with measurement performance criteria from the QAPP*	Validation Report – Includes qualified data – May be part of other report such as RI/FS
Usability Assessment*	Assess and document usability to meet project quality objectives.	- Sampling - Analysis	III. Assess usability of data by considering project quality objectives and the decision to be made*	Usability Report – May be part of other report such as RUFS

Table 8. Data Review Process Summary

*The scope of the term or the step involved is an expansion of current practice.

Data Validation Question	Data Suitability Question	Examples
Have the analytical methods been followed properly?	Now that data are available, do we still think that these were the appropriate analytical methods?	Were there extreme matrix interferences? Were matrix spike/matrix spike duplicate recoveries unusually low using these methods?
Have the detection limits been calculated properly?	Are these detection limits adequate for the goals of this project?	Were detection limits appropriate (do they cover the threshold of concern for each compound)? Were the technical basis for calculation of detection limits documented correctly?
Have MQO goals, such as precision and bias, been achieved?	Based on the available data, do these MQO goals still seem reasonable?	Were the initial calibration criteria (response factors, precision, correlation coefficient) appropriate for these analytes?
Are the appropriate data points flagged with qualifiers?	What do patterns in the qualified data suggest about the overall data set?	For data that fall between the detection limit and the quantitation limit, has the laboratory provided numeric values rather than flags only? How do you interpret flags indicating contaminated blanks when the real samples have the same contaminants?

Table 9. Data Validation Versus Data Suitability

What is Data Usability?

☆ Documented in a report
 ☆ Performed as part of the data review
 ☆ Adequacy of data for making decisions
 ☆ Assessing if the execution of the process and resulting data meets the project quality objectives

Advanced Systems, Inc.

Advanced Systems, Inc.

Unique to each Project

☆ Defined at start of project
 ☆ Personnel identified
 ☆ Responsibilities defined
 ☆ Process documented

Advanced Systems, Inc.

History

☆Data validator uses

Professional judgment to determine if there is any need to qualify data which were not qualified based on the QC criteria previously discussed."

Advanced Systems, Inc.

☆ Often the default ☆ Applicable to Superfund Contracts ✓ not others

☆ Does not address:
 ✓ Systematic planning
 ✓ Sampling
 ✓ QA Oversight
 ✓ Non CLP methods
 ✓ Data Usability

Advanced Systems, Inc.

Data Review Today

Verification/Validation/Usability
 Detailed investigation of particular data records that need special interpretation
 Appropriate to meet project requirements
 Does the data support the decision?
 What are the limitations on the data use?
 How confident is the decision based on the available data?

 ☆Usability follows verification/validation
 ☆Process defined
 ☆Documentation defined
 ☆Personnel qualification defined
 ☆Trends, relationships, and anomalies presented

Advanced Systems, Inc.

Items to Consider

Evaluative Procedures to Assess
 Overall measurement error
 Data quality indicators
 Measurement quality objectives

Compare with measurement performance criteria from the QAPP*	Validation Report – Includes qualified data – May be part of other report such as RUFS
Usability Assessment*	Assess and document usability to meet project quality objectives.	- Sampling - Analysis	III. Assess usability of data by considering project quality objectives and the decision to be made*	Usability Report – May be part of other report such as RI/FS

Table 8. Data Review Process Summary

*The scope of the term or the step involved is an expansion of current practice.

Validation vs Suitability

☆ Validation Have the analytical methods been followed properly?

 Have the detection limits been calculated properly? ✓ Suitability
✓ Were these the appropriate analytical methods?

 Are these detection limits adequate for the goals of this project?

Table 9 EPA QA/G-8 November 2002

Advanced Systems, Inc.

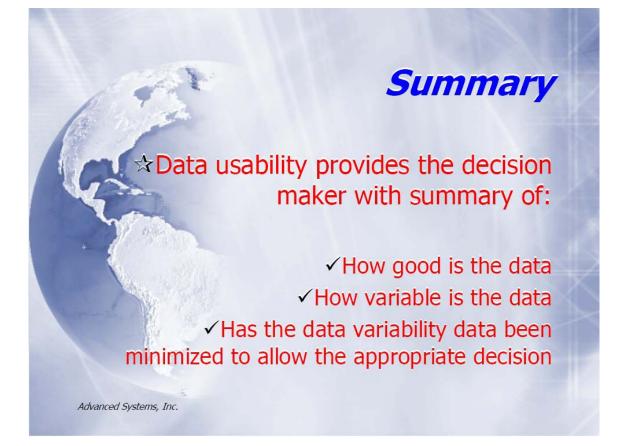

Validation vs Suitability

 ✓ Validation
 ✓ Have MQO goals been achieved (Precison, bias)?

 Are the appropriate data points flagged with qualifiers? ✓ Suitability✓ Do the MQO goalsstill seem reasonableto make decision?

 What do patterns in the qualified data indicate about the overall data set?

WEB-EDMS SYSTEM

Garrison, Grant E.; Integrated Environmental Services, Inc. Young, Michael Dr.; Integrated Environmental Services, Inc.

Complex site cleanups involve massive amounts of data, often gathered at a large cost. Despite the investment in the data, uncertainties remain as to the actual characteristics of the site due to the real world constraints of limited resources for investigations. Dynamic sampling strategies that allow real time changes in sampling plans in response sampling results offer significant promise of the ability to save time and money while reducing uncertainty associated with limited data gathering. However, achieving those objectives requires a real-time data management system that can easily handle both the challenges of database management and data analysis to support decisions to modify sampling plans on-the-fly. This paper will describe one such system developed for the private sector that is now in use on Department of Energy facilities.

Integrated Environmental Services, Inc., in managing large scale, complex site cleanups for aerospace and defense, oil and gas, and real estate clients, recognized the need for an all-in-one, intuitive and user friendly system. Working with experts in GIS, 3D data visualization, health risk assessment, environmental engineering and computer programming fields, Integrated developed web-based Environmental Data Management System (webEDMS). This patented software is able to seamlessly integrate the components of the RI/FS process. The webEDMS application provides a cradle-to-grave data management solution for investigation and cleanup of DOE sites. The system stores and organizes project data from a variety of sources (real-time monitoring devices; electronic databases including laboratory reports; hardcopy; maps; photographs; schedules, budgets, etc.).

WebEDMS provides team members the ability to convert hard-earned massive amounts of site data to valuable information without searching through hardcopy libraries of project reports and re-keying the information. The project team gains insight from the data by understanding the nature, extent and changes of site contamination over time, via 3-D visualization. All site information is linked and searchable through one single application. As it is a web-based system, this wealth of information is available to all relevant project team members located throughout the country. This transparency and access is important not only to allow the entire project team to participate in the dynamic sampling strategy decision making process, but also to building trust in the site conceptual model that allows decisions to be reached with the confidence of all parties.

WebEDMS goes even further by automating the risk assessment process and allows the user to conduct human health risk assessments with just a few clicks of the mouse. Consequently, sampling decisions can be made rapidly with a full understanding of site conditions. The user can choose the appropriate media type and the contaminants of concern. The user also can chose Federal or State-specific toxicity criteria, specific receptors associated with the land use scenarios, and the applicable exposure pathways. The health risk assessment module of the webEDMS is designed based on USEPA default parameters; however, modifications to these parameter are allowed. The user can conduct risk assessments that result in site specific Health Based Remedial Goals (HBRGs) or calculate the site-specific cumulative incremental lifetime cancer risk.

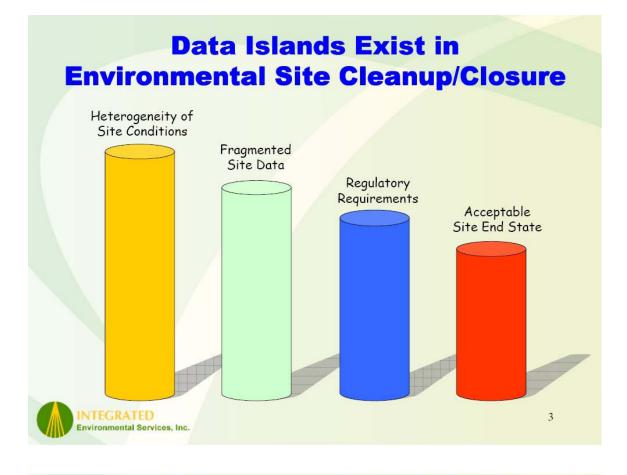

Web-based Environmental Data Management System – A System for Real Time Environmental Data Management and Risk Assessment

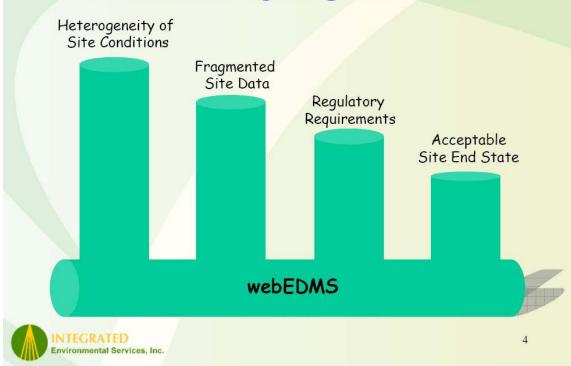

Objectives

- Introduce and Demonstrate Patented webEDMS software
- Discuss Advantages of Real-Time Risk Assessment in Reducing Uncertainty
- Discuss Synergies between Triad & webEDMS

webEDMS Connects Data Islands and Generates Synergistic Value

Overview of webEDMS

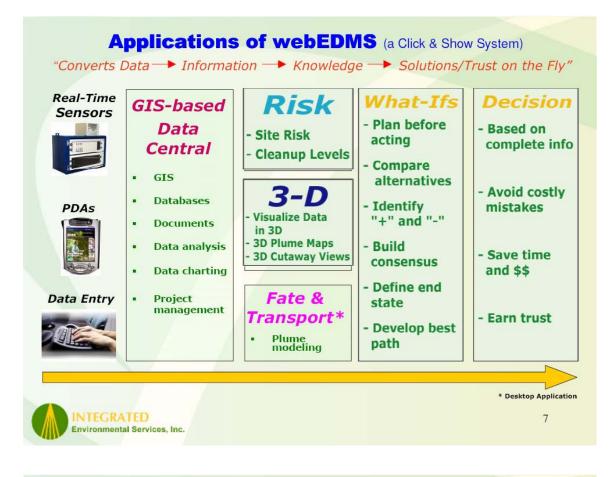

- The most powerful, integrated, proven and user-friendly system on the market with realtime "Informatics" (integrated and seamless data acquisition, analysis, warning, reporting, collaboration and decision support) capabilities
- The only web-based, cradle-to-grave, realtime data sharing and communication tool that empowers the user to make scientifically defensible decisions based on complete, upto-the-minute site information

INTEGRATED Environmental Services, Inc.

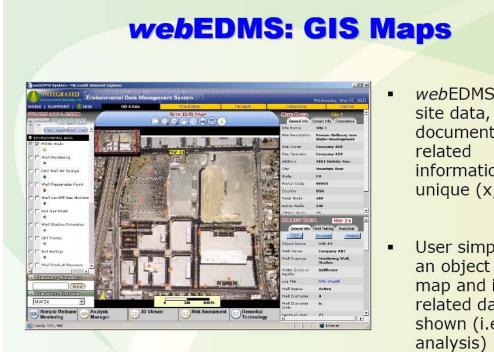

Benefits of webEDMS

- Provides transparency to the entire RI/FS process, thus enhances project quality and streamlines regulatory reviews and approvals
- 3D data visualization helps the user understand complex site conditions, identify impediments to site closure and design the most cost-effective remedial plan
- Performs real-time health risk assessments to guide site activities and ensure acceptance of the site end state/desired outcome
- All these lead to cheaper, quicker and safer site cleanup and closure

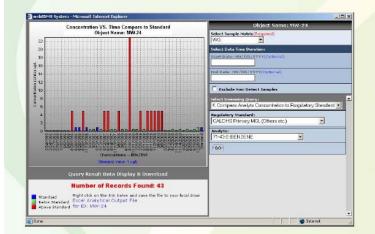

- webEDMS links site data, documents and information to its unique (x,y,z)
- User simply clicks an object on the map and its related data is shown (i.e. object

Environmental Services, Inc.

- It makes risk calculations transparent to laymen
- It builds trust with stakeholders
- Real time risk calculation saves time and money
- It provides much needed what-if management tools to the team

The Three Triad Elements

- Systematic project planning

 Laying a foundation for a scientifically defensible approach to proposed project activities

- Dynamic work strategies

 Real-time modification of work plans in response to sampling data, saving time and money

- Real-time measurement technologies

Any technology that supports real-time decision making

TRIAD TO INCREASE CERTAINTY IN REMEDIATION DESIGN

Mack, James; New Jersey Institute of Technology

For a site cleanup project in New Jersey, real-time analytics played a key role in filling the data gaps creating large uncertainties when estimating the volume of petroleum material in the subsurface, a critical input to successful site cleanup. The contaminants consisted of TPH, PCBs, and chlorinated solvents. The analytical techniques used included in situ petroleum detection and characterization using a fuel fluorescence detector (FFD), PetroFlag test kit and routine laboratory analysis for TPH, and mobile laboratory GC-MS for Aroclors and chlorinated VOCs.

A demonstration of methods applicability (DMA) was used to establish a predictive relationship between the complex FFD's fluorescent response and site-specific petroleum fingerprints. This predictive relationship permitted real-time, semi-quantitative, in situ, high vertical and areal sampling density logging of the subsurface to locate and bound quantities of separate and mixed "pools" of fuels and oils for appropriate remedial design.

This project's dynamic work strategy (which was supported by real-time, high-density analytics) was able to resolve in 3 weeks of field time data gaps that had been unsuccessfully addressed for over 10 years.

Triad and Remediation Design

James Mack New Jersey Institute of Technology Newark, New Jersey (973) 596 5857 mack@adm.njit.edu

Remediation & Uncertainty

- Converting Investigation Information Into Hard Remediation Design Is Fraught With Peril
- Do You Know The Following:
 - Volumes Of Impacted Material
 - Contaminate Concentrations/Mass Requiring Treatment
 - Application Location (Is It In The Right Place)
 - Performance Predictions
 - Operating Timeframe
- It All Comes Down to One Thing: Can You Predict the Remediation Cost With Confidence

Triad & Uncertainty Management

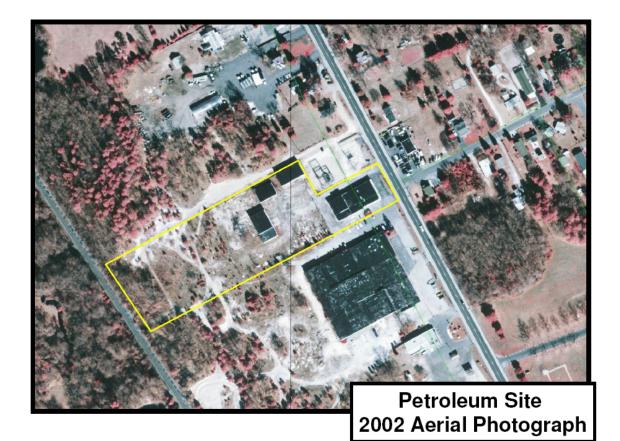

- Triad Focuses On Systematically Improving The CSM, Than Simple Regulatory Compliance
- Sample Representativeness Is As Important As Analytical Data Quality
- Collaborative Data Sets Increase Sample Density And Accuracy
- Data Imaging/Visualization Improves Communications & Agreement On Remediation Objectives
- All Leads To: Increased Confidence In Remediation Design, Implementation & Costing

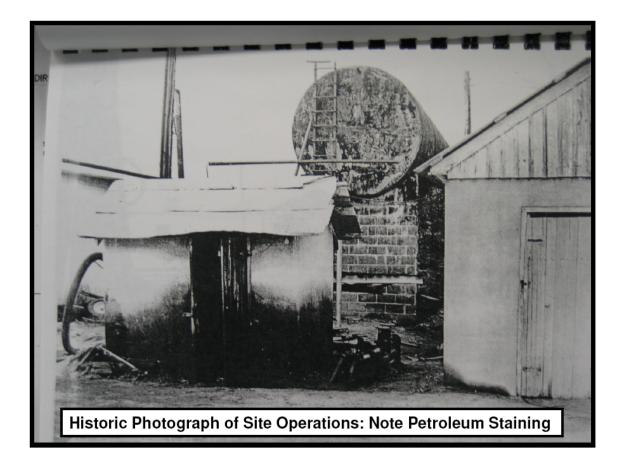

Case Examples:

 Petroleum Distribution Facility
 Former Chemical Manufacturing Facility

Site Background

- Located in Franklinville, New Jersey
- Site size: Approximately 10 ac
- Long History of Petroleum Product Handling (Since 1940's)
- Also Was a Waste Oil Management Facility in Mid-70's
- Very Poor House Keeping Resulted in Extensive Releases by Various Hydrocarbons

Site Historical Operations Relative to COCs & Source Areas

Initial Conceptual Site Model

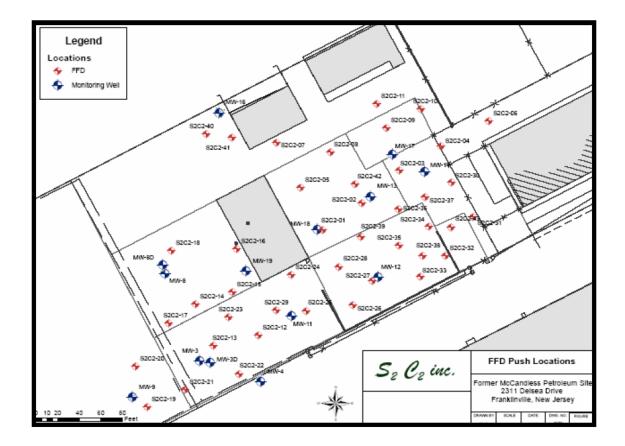

- Oil was released at site during past operations
 From 1947 to 1972: home heating oil (No. 2 oil)
- PCBs & solvents were dissolved in waste oils brought to site in 1972-1974 which released to environment
- Oil (w/PCBs & solvents) migrated downward to water table and accumulated on top of watertable
- PCBs & VOCs in the oil begin to mix with and VOCs dissolve into groundwater (VOCs dissolve; PCBs mix w/ top of water table)
- Oil layer becomes an important interval to clearly delineate because it is likely the source of PCB & TCE in groundwater

Basic Field Activities Sequence

- <u>Step 1:</u> FFD profiles & modeling to rapidly define oil layers & create 3-D image
- <u>Step 2</u>: VOC in groundwater to confirm no site DNAPL source
- <u>Step 3:</u> Soil sampling to delineate PCBs in vadose zone & PCBs/oil in the saturated zone
- <u>Step 4</u>: Bulk sampling in 3 areas (bulk density, porosity, natural oxidant demand; permeability; grain size distribution, etc.) to evaluate potential for in-site treatment

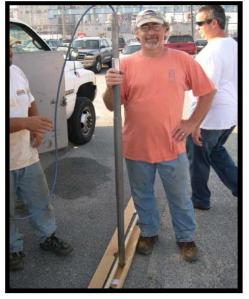

Field Activities

- Three weeks of field work in March 2006
- 43 FFD depth profiling locations
- 66 groundwater samples tested on-site for VOCs at 18 locations (variable depths)
- PDB in three existing monitoring wells
- 37 soil borings
- 85 soil samples for PCBs
 - Most samples analyzed in the field using mobile lab
 - Select group of samples sent to off-site lab to verify field analyses (five PCB & seven TPH)
- 3 treatability samples

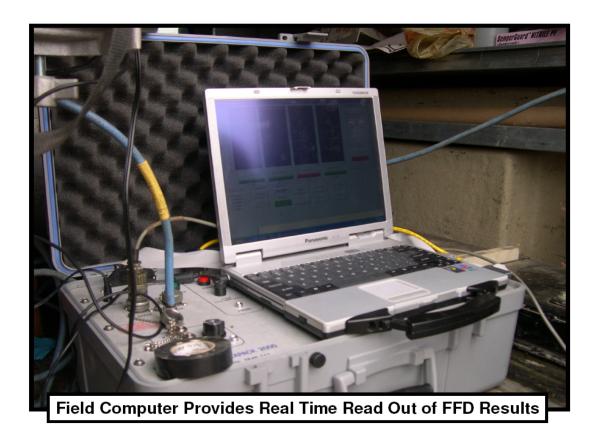

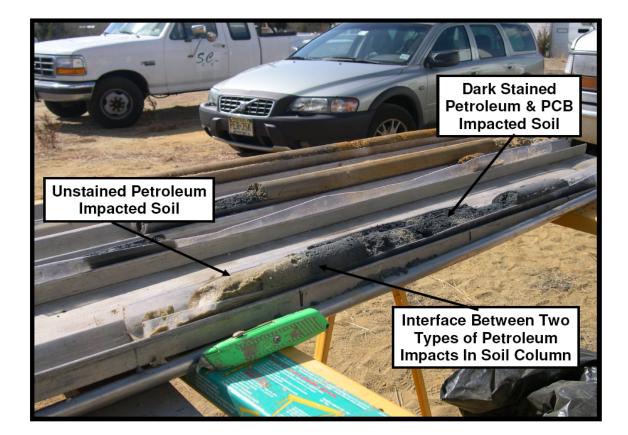

Fuel Florescence Detector (FFD)

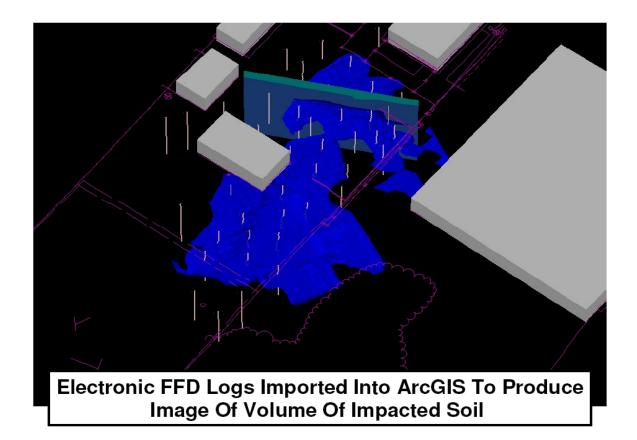

- Primarily for petroleum hydrocarbon delineation
- Direct push Ultraviolet Florescence (UVF) probe (push only)
- UV lamp in probe causes hydrocarbons to fluoresce
- Fluorescence captured by probe and converted to electronic signal
- Continuous log of electronic signal created
- Signal strength corresponds to concentration and can be imported to ArcGIS
- Impact area can be imaged by classifying according to signal strength

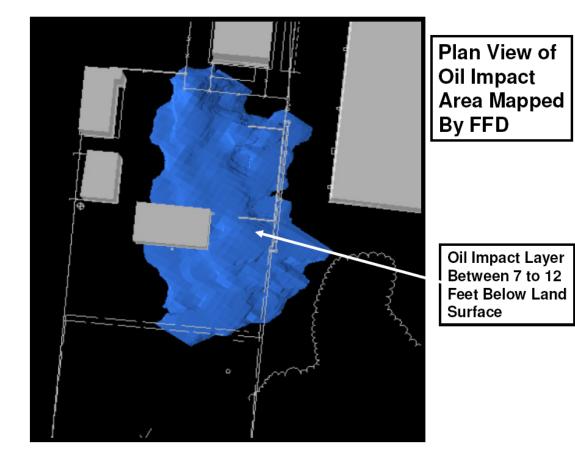

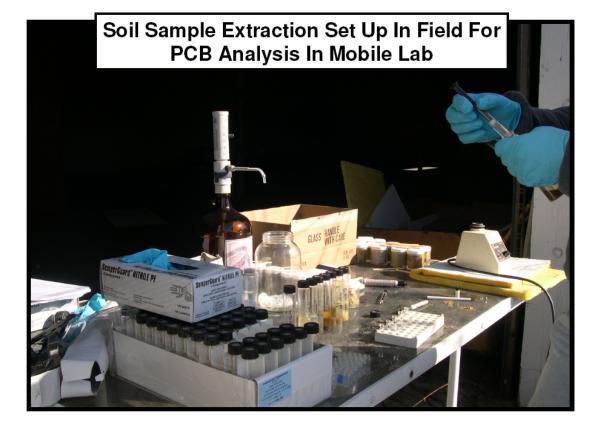

Fuel Fluorescence Detector

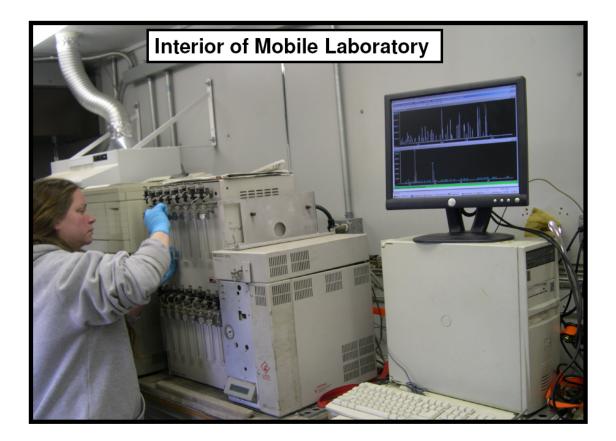

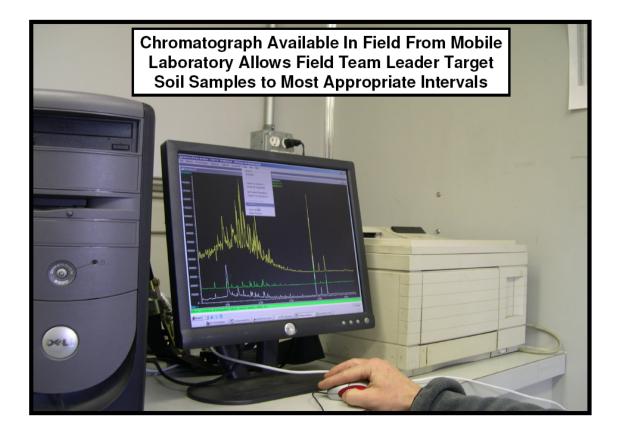

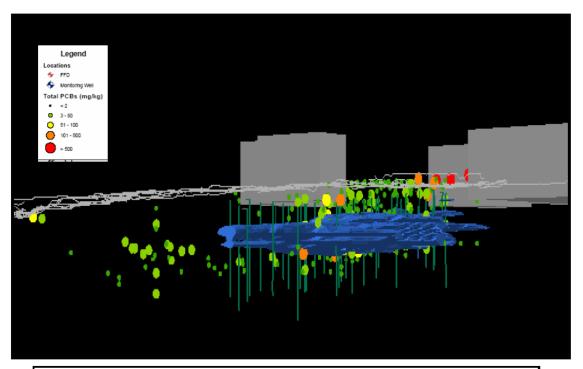

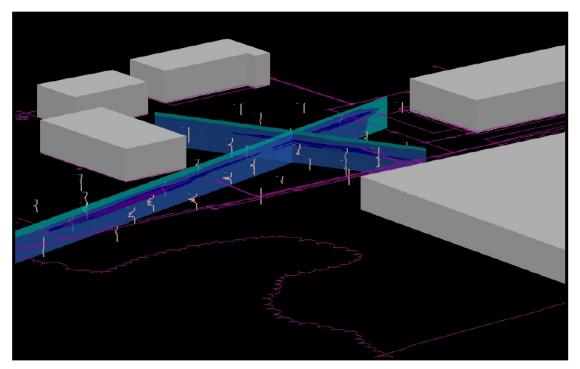

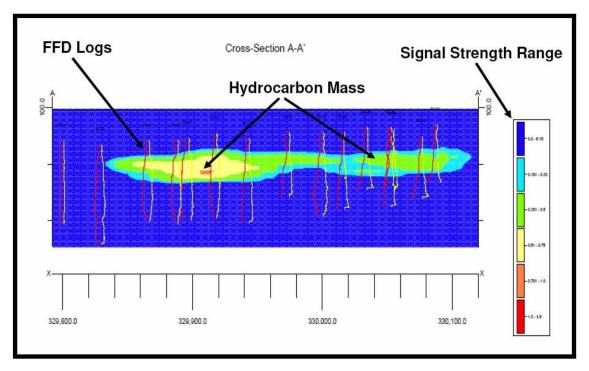

Cross Section Of the Oil Impact Layer With PCB Soil Sample Results Illustrated as Colored Circles

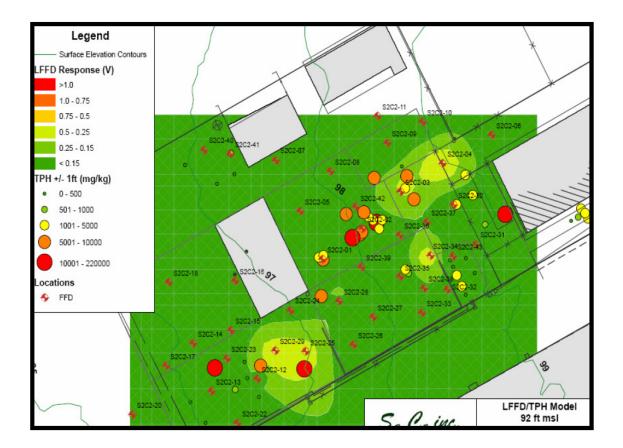

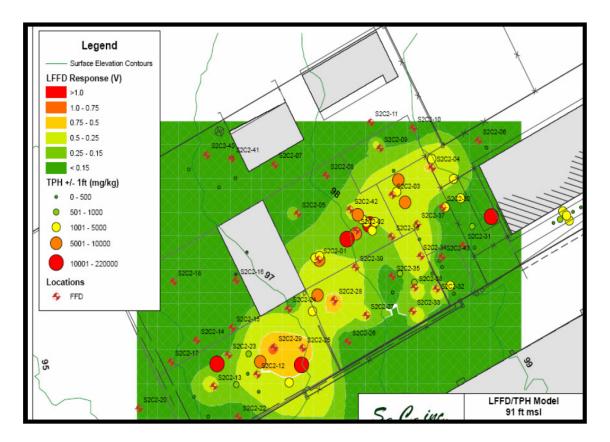

Fence Diagram Through the Hydrocarbon Mass: First Step in Converting Investigation Information & Images into Engineering Diagrams

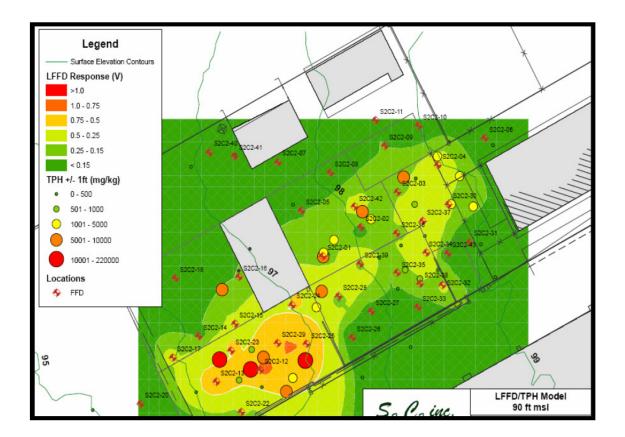

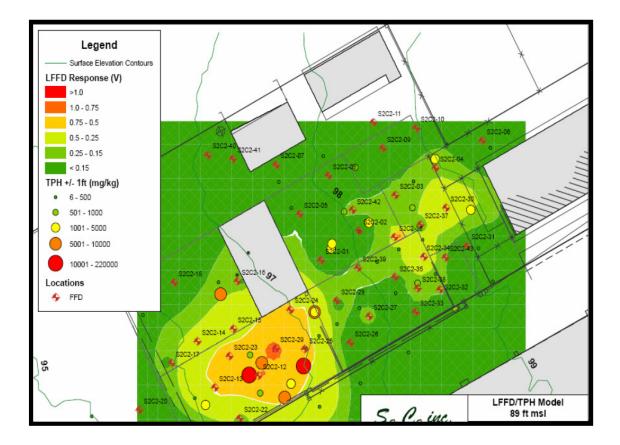

Cross Section Through The Hydrocarbon Mass Mapped By The FFD: Starting Basis for Ozone Sparging System Layout

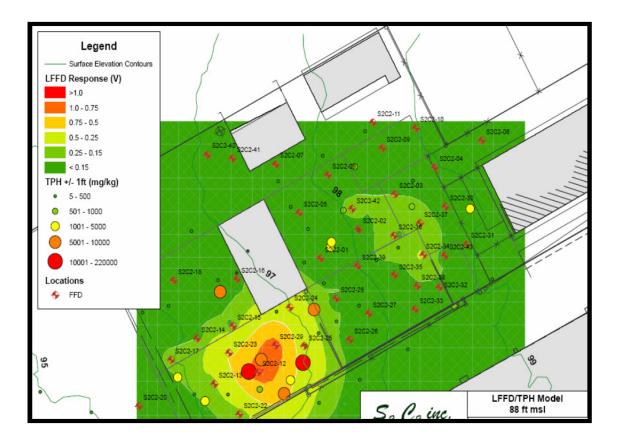

Horizontal One Foot Slices Through the 3D Imaged Hydrocarbon Impact Zone: Moving Downward Through Model

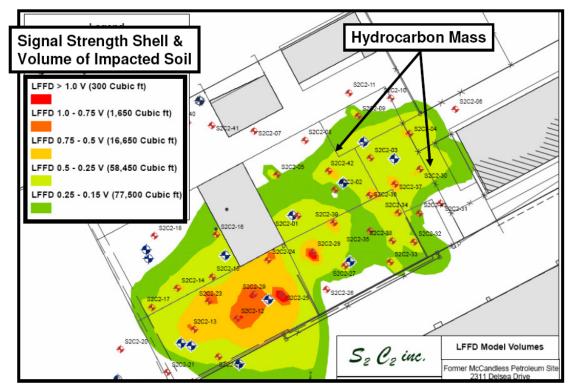

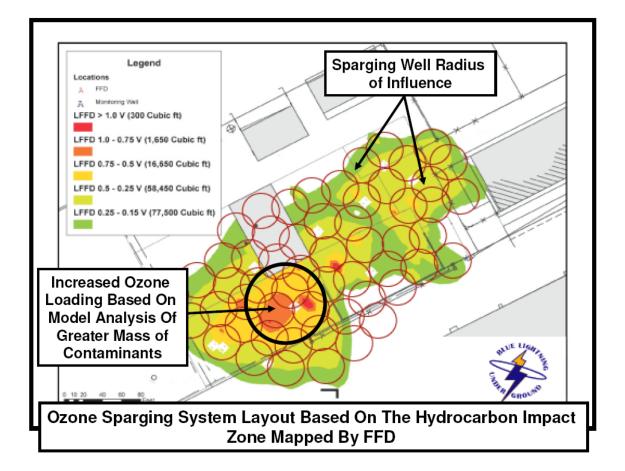

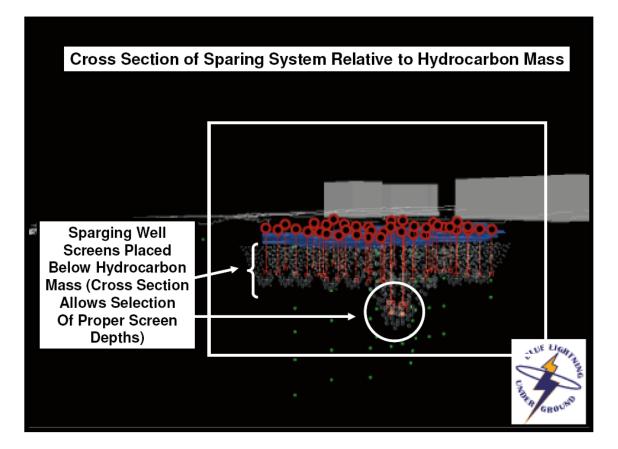

Horizontal Slices Are "Stacked" To Determine The Volume of Impacted Soil Within Each Signal Strength Shell, Which Is Then Converted to Mass In Place

Summary: Converting Investigation Imaging to Hard Engineering

- Investigation Images Depict Findings Relative To Objectives Such As Impact Area, Migration & Exposure
- Remediation Design Requires Images To Be Converted To Engineering Data Such As Mass, Volumes & Dimensions
- Triad Provides The Sampling & Analytical Density To Develop Detailed Remedial Designs
- Process:
 - Convert 3D Images To Plan & Cross Section Views
 - Correlate Image Shells W/ Concentrations To Obtain Mass & Volume Estimates
 - Develop Layouts Using Plan & Cross Section Views
 - Adjust Treatment Material Loading Based On Mass Distributions

Overall Summary

- Collaborative Data Sets Consisting Of Information From Multiple Testing Methods Provides Increased Detail Of Impact Area
- Increased Detail Enables Engineers To Design Remediation Applications With Greater Confidence
- Transition From Investigation To Hard Design Quicker And Easier Using Triad Based Computer Imaging

Air

NATIONAL PICTURE OF AMBIENT AIR TOXICS

Hafner, Hilary R.; Sonoma Technology, Inc. McCarthy, Michael C.; Sonoma Technology, Inc.

Ambient air toxics measurements for hazardous air pollutants collected in the United States from 1990 to 2003 were analyzed for diurnal, seasonal, and/or annual variability and trends. Visual and statistical analyses were used to identify and quantify temporal variations in air toxics at national and regional levels. A major issue with air toxics data that affect our ability to identify and quantify trends is that much of the data is below method detection limits (MDLs). Of the 39 air toxics included in this study, about 40% of the measurements were reported as a substituted value (e.g., MDL, MDL/2, zero). Also, some of the data that appear to be below MDL are not indicated as such. Furthermore, many of the species MDLs are above the cancer benchmark for that specie which makes it difficult for analysts to assess risk. In this study, data that were clearly substituted were considered invalid; we set data completeness criteria for inclusion of data in an analysis.

Four different diurnal variation-patterns were identified for fourteen air toxics and three different seasonal patterns were identified for thirty-four air toxics. Sufficient data exist to quantitatively assess long-term trends of 15 air toxics. Urban concentrations of o-xylene, benzene, 1,3-butadiene, chloroform, carbon tetrachloride, cadmium (tsp) and lead (tsp) were shown to have declined. Urban concentrations of tetrachloroethylene, trichloroethylene, and acetaldehyde concentrations declined on average, but were not statistically significant; formaldehyde, chromium (tsp), and arsenic (tsp) concentrations increased on average, but were not statistically significant. Urban concentrations of methylene chloride, and manganese (tsp) showed a mix of increasing and decreasing trends, with no clear national trend. This presentation will show a National view of ambient air toxics concentrations in the United States, put these concentrations in perspective relative to health benchmarks, and discuss data needs as the National Air Toxics Trends Site (NATTS) program matures.

What Is the National Picture of Air Toxics Concentrations?

Hilary R. Hafner Michael C. McCarthy

Presented at the National Environmental Monitoring Conference Arlington, VA

August 29, 2006

STI-2992

- Air toxics have been measured at several hundred sites since 1960 by state, local, and tribal air pollution control agencies, but little exploration of the data at a national scale had been performed prior to 2000.
- In 2000, a long-term data analysis project was initiated to guide development of a national air toxics monitoring program and subsequently to investigate national-scale air toxics trends.
- Since 2000, the EPA and the states have worked together to establish the National Air Toxics Trend Sites (NATTS) program, numerous community-scale monitoring studies, and a multi-year data analysis project.

What Are the Most Important Air Toxics?

- They are based on National Air Toxics Assessment 1999 (NATA99) riskweighted rankings of people exposed to air toxics.
- Top 10 rankings are for number of people exposed to cancer risk greater than 10⁻⁶, 10⁻⁵, and 10⁻⁴.

MDL = method detection limit, often calculated as the analytical blank + three times the standard instrument error (noise), yielding a value where

(NDL = Include declation limit, or the calculated as the analytical blank + three times the standard instrument entry (noise), yredning a value where concentrations are detectable with 9% confidence.
* Indicates pollutant's data quality was downgraded due to known measurement or risk standard instrument entry (noise), yredning a value where to 2005, and its data quality ranking was downgraded due to known measurement or risk standard instrument entry (noise), yredning a value where to 2005, and its data quality ranking was downgraded from moderate (based on data above MDL) to unacceptable. Chromium PM_{2.5} and Nickel PM_{2.5} do not measure the toxic component directly (Chromium VI or Nickel subsulfide) and therefore data quality was downgraded from poor (based on data above MDL) to unacceptable.

- The monitoring community has done a great job of getting spatial coverage at hundreds of sites in the United States.
- Unfortunately, the data being collected are not very useful for risk analyses (except for identifying upper limits on some concentrations) or spatial variability analyses for most species.
- Better detection limits are needed.
 - Should we spend more money on better detection limits rather than on routine monitoring?
 - How can we improve collection or analysis methods to acquire more useful data?
 Longer sampling times?
 - Improved analytical methods?

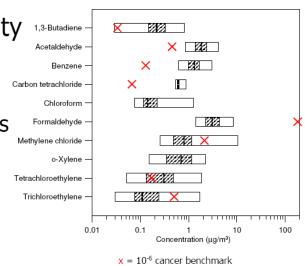

- More pollutant-specific methods?

What Can We Do With the Data?

Collection and Analysis of Acrolein using Compendium Method TO-15

Julie L. Swift, Mitch Howell, Donna Tedder, Raymond Merrill

Eastern Research Group, 601 Keystone Park Drive, Suite 700, Morrisville, NC 27560

ABSTRACT

Acrolein, because of its polarity and reactivity, is recovered more efficiently in canister samples using EPA Compendium Method TO-15 with Gas Chromatography/Mass Spectroscopy (GC/MS) and selective ion monitoring (SIM) than the previously used Compendium Method TO-11A. Determination of acrolein by Method TO-11A is less accurate because of the low acrolein capture efficiency and the tautomerization of the acrolein hydrazone derivative on acidified 2, 4-dinitrophenylhydrazine (DNPH) cartridges. Eastern Research Group (ERG) has demonstrated this superior performance of canister sampling through the results of a study that introduced a gaseous acrolein standard, representative of "real world" samples, concurrently into DNPH cartridges and canisters. A field study comparison of the collection efficiency of acrolein using Method TO-15 and Method TO-11A will be presented for samples simultaneously collected throughout the country for one year in canister and cartridge samples. Data using Method TO-15 collection and analysis of ambient air across the United States will be presented to show the recovery of acrolein in canister samples. Audit results will be presented proving the accuracy of acrolein from canister samples using Method TO-15.

INTRODUCTION

Acrolein is listed as one of the four core compounds for the National Air Toxics Trends System (NATTS) throughout the country. Because of this, and because of the reactivity and toxicity of acrolein in ambient air, ERG has been studying new techniques to collect and analyze acrolein more accurately. Method TO-11A has been the standard method the analysis of aldehydes in ambient air. ERG has not reported analytical results for the measurement of acrolein since 1999 because of its unstable retention on the adsorbent cartridges used for Compendium Method TO-11A. An Addendum to Method TO-11A was issued March, 1999 to remove acrolein from the analyte list. Recently, ERG has determined that acrolein can be analyzed more accurately using Compendium Method TO-15 from air samples in canisters. Method TO-15 is an analytical method currently used for the sampling and analytical procedures for the measurement of subsets of volatile organic compounds that are included in the 1989 hazardous air pollutants (HAPs) listed in the Title III of the Clean Air Act Amendments of 1990.

The following data present the comparison of two compendium methods as well as the precision and accuracy following Method TO-15.

Methodology

DNPH treated cartridges and SUMMA canisters were used to collect ambient samples at the same sampling site. These samples are taken at the same time on the same sampling systems. The canisters and cartridges were collected for 24 hours. Canisters collect 6L of whole air, whereas the carbonyl tubes concentrate and stabilize carbonyl compounds from a volume of air. ERG collects and analyzes all canister samples at a vacuum from 1 to 12 inches of Hg to

ensure volatile organic compounds remain in the vapor phase. If the canister is pressurized, condensation of water from high-humidity samples may cause fractional losses of polar, water-soluble compounds.

Method Development – Method TO-11A

Method TO-11A, the standard method for the analysis of aldehydes in ambient air, demonstrates low recovery for acrolein. A recent study conducted by ERG used a certified standard of gaseous acrolein rather than liquid DNPH derivative spikes to simulate a real world sample. The certified cylinder was used to sample underivatized acrolein through a sampling system onto the DNPH cartridges.

Four sample sets (i.e., duplicate paired carbonyl cartridges) were collected from a common test manifold, one set every 24 hours over a period of 4 days. After the samples were collected, the cartridges were extracted within 7 days of sampling and analyzed within 30 days of extraction. Table 1 presents the sample recovery results. Because the recovery was consistently below acceptable limits, ERG decided to evaluate acrolein analysis by TO-15.

	Acrolein ^a (two peaks)
Sample	Conc. Recovered (ppbv)	Percent Recovery
Sample Run 1 - Primary	2.55	43%
Sample Run 1 - Duplicate	2.18	37%
Sample Run 2 - Primary	2.59	44%
Sample Run 2 - Duplicate	2.33	39%
Sample Run 3 - Primary	2.47	42%
Sample Run 3 - Duplicate	2.32	39%
$Mean \pm Standard Deviation$	2.41 ± 0.16	$41\%\pm3\%$

Table 1: Carbonyl Recovery Data -Modified Method TO-11A, Gaseous Samples

^a Acrolein nominal concentration is 5.92 ppbv.

Method Development - Method TO-15

Acrolein was measured using Method TO-15 without altering the analytical method currently used to determine the toxics compounds reported to the EPA for the Urban Air Toxics Monitoring Program (UATMP). Acrolein was stable in calibration standards and could be separated from other Method TO-15 compounds using conditions recommended in the method.

The goal was to try to determine acrolein at low enough concentrations (at or below risk levels) without major modifications to the current method. Reaching low detection limits required the use of Gas Chromatography/Mass Spectroscopy (GC/MS) with selective ion monitoring (SIM). MDLs are determined at the ERG analytical laboratory using 40 CFR, Part 136 procedures. ERG's experimentally determined MDL for acrolein is 0.10 ppbv (0.23 μ g/m³) for 2006.

To evaluate field sample collection, a canister sample was collected through a NATTS TO-15 sampler spiked with gaseous acrolein. Results from the analysis of this single sample showed acceptable recovery for acrolein of \pm 10 percent.

ERG then examined acrolein recovery and stability using Method TO-15. Multiple canisters from different manufacturers were spiked with know amounts of acrolein and analyzed several times over a period of 4 weeks. The relative percent difference (RPD) between time zero (Week 1) and subsequent analysis for this study is shown in Table 2.

Sample	Relative	Concentration		RPD	
ID	humidity	(ppbv)	Week 2	Week 3	Week 4
1-1	1.09/	Low - 0.5	10.5%	ND	ND
1-2	10%	High - 10	5.04%	-4.47%	9.68%
1-3	800/	Low - 0.5	0%	ND	ND
1-4	80%	High - 10	0%	-2.05%	-0.79%
2-1	100/	Low - 0.5	2.74%	-2.67%	-2.67%
2-2	10%	High - 10	NA	8.76%	14.8%
2-3	80%	Low - 0.5	8.89%	-2.11%	-27.5%
2-4		High - 10	0.29%	-0.66%	13.9%
3-1	100/	Low - 0.5	2.99%	-2.90%	-16.2%
3-2	10%	High - 10	7.50%	16.2%	27.1%
3-3	80%	Low - 0.5	-8.00%	40.0%	ND
3-4	80%	High - 10	-10.2%	-16.7%	10.1%
4-1	1.09/	Low - 0.5	-26.2%	-36.9%	-43.0%
4-2	10%	High – 10	3.65%	5.56%	3.56%
4-3	0.00/	Low - 0.5	7.06%	-6.59%	-16.7%
4-4	80%	High - 10	-0.35%	-9.67%	12.5%

Table 2: Acrolein Stability in Canisters Expressed in RPD

NA = Not applicable - analytical malfunction.

ND = Not detected.

NOTE: Results listed in **bold** are outside the required RPD of 25%.

Acrolein recovery over four weeks was within acceptable range. The stability at the low concentration and humidity is less than the high concentration and humidity. This study supports the ability to report acrolein concentrations for NATTS and UATMP sites across the country.

After the stability study was completed, the Rhode Island Department of Health Laboratory reported acrolein concentrations increased in ambient air canisters within a short period of time after collection. To investigate the Rhode Island observation, ERG performed a short-term stability study. Grab samples were taken on an overpass above a heavily traveled highway. This

allowed elevated levels of acrolein from mobile sources emissions to be present in the canisters. Table 3 presents the results of this study. Because of the close chemical structure of acrolein and 1,3-butadiene, recoveries for both compounds are presented. Results are presented for the analysis performed directly after sampling, 24 hours after sampling, and pressurized samples. As shown, there was no statistical differences in the results with the exception of Canister 2080, which had variance over the NMP data guidelines of 25%.

Compendium Method Comparison

ERG has collected acrolein from the National Monitoring Program sites (NMP) since July 2005 following Method TO-15. To demonstrate the percent differences between the two methods, Table 4 presents results for Method TO-11A versus TO-15. Percent recovery of Method TO11A assumes the Method TO-15 results represent acrolein concentration in these ambient air samples.

Site	Date	TO-11A (ppbv)	TO-15 (ppbv)	% Recovery of TO-11A
Bountiful, UT	9/13/05	0.114	3.17	3.6%
Loudon, TN	10/13/05	0.040	1.10	3.6%
Providence, AL	10/19/05	0.059	1.20	4.9%
Birmingham, AL	10/19/05	0.137	1.46	9.4%
Shillar Park, Chicago, IL	10/31/05	0.085	1.08	7.9%
Madison, WI	11/12/05	0.049	0.47	10.4%
Barceloneta, Puerto Rico	11/12/05	0.024	0.84	2.9%
Minneapolis, MN	11/18/05	0.018	1.21	1.5%
Camden, NJ	12/24/05	0.186	0.78	23.8%
New Brunswick, NJ	12/30/05	0.040	1.18	3.4%
Sioux Falls, SD	2/28/06	0.089	0.56	15.9%
Grand Junction, CO	3/24/06	0.099	0.58	17.1%

Table 4: Method TO-11A versus Method TO-15

Site	Date	TO-11A (ppbv)	TO-15 (ppbv)	% Recovery of TO-11A
Austin, TX – site 1	4/23/06	0.054	0.48	11.3%
Austin, TX - site 2	4/23/06	0.037	0.39	9.5%
Austin, TX - site 3	4/23/06	0.035	0.58	б.0%
Austin, TX - site 4	4/23/06	0.036	0.53	6.8%
Austin, TX - site 5	4/23/06	0.089	0.45	19.8%
Custer Park, SD	5/17/06	0.044	0.74	5.9%
Elizabeth, NJ	5/29/06	0.192	0.66	29.1%
Tulsa, OK	5/29/06	0.121	0.82	14.8%

The recoveries of acrolein are clearly much lower for Method TO-11A than for Method TO-15 in a real field samples.

Method TO-15 Field Sample Results for Acrolein

Nineteen NMP sites collected samples from July 2005 to July 2006. Some monitors were placed near the centers of heavily populated cities (e.g., Chicago, IL and St. Louis, MO), while others were placed in moderately populated areas (e.g., Madison, WI and Custer, SD). Acrolein concentrations measured during this time varied significantly from monitoring location to monitoring location. The proximity of the monitoring locations to different emissions sources, especially industrial facilities and heavily traveled roadways, often explains the observed spatial variations in ambient air quality.

A total of 1,450 acrolein measurements (including duplicate and replicate samples) were detected at the 43 NMP sites from July 2005 to July 2006. Five hundred and sixteen of these samples were taken at four sites during the clean-up after Hurricane Katrina. Of the 1,450 acrolein measurements, 54 % of these results were detects and 1.2% of these concentrations were below the MDL. The average acrolein concentration was 1.54 μ g/m³. Table 5 presents the sample count, maximum value, minimum detected value, median, mean for this data set.

	Frequency	Maximum Value	Minimum Value	Median	Average
Site ID	of Detects	(µg/m3)	(µg/m3)	(µg/m3)	(µg/m3)

Data from the NMP sites are shown in Figure 1. The highest concentration were taken at El Paso, TX, at 9.59 ppbv (22.57 μ g/m³). Because of the large amount of samples taken for Hurricane Katrina, data from these sites are shown separately in Figure 2. These samples were collected on a 1-in-1 and 1-in-3 day schedules. These data are presented in Figure 2 using the same scale as Figure 1. Acrolein results from the NMP and Katrina sites are relatively the same and show similar increases or decreases over time.

Acrolein Results for All Sites (µg/m³)

Acrolein Results for Hurricane Katrina Clean-up Sites (µg/m⁸)

Data Quality Control and Assurance

An audit containing acrolein was prepared in November, 2005 by US EPA and sent to ERG for analysis. Table 6 presents a summary of the audit report. The acrolein concentration determined by ERG resulted in a 22.3 RPD from the nominal value spiked in the canister. The 'True' value was based on the results of 3 analyses performed by Alion/EPA(ORD).

Compound	ERG (ppbv)	True (ppbv)	% Difference	Uncertainty
Acrolein	1.48	1.21	22%	± 11.3%
1,3-Butadiene	1.84	1.44	28%	± 0.2%

Table 6: Acrolein Audit Results

NOTE: The percent uncertainty is the coefficient of variation for the three replicate analyses.

Precision of the analytical and sampling technique was determined by the analysis of duplicate sampling episodes and replicate analysis. A duplicate sample (i.e., a sample collected simultaneously with a primary sample using the same sampling system) provides information on the potential for analytical variability. The duplicate and replicate analysis results were complied from sites sampling in the NMP from July, 2005 through June, 2006.

The data are presented in Relative Percent Difference (RPD) and the Coefficient of Variation (CV). The RPD expresses average concentration differences relative to the average concentration detected during replicate analyses. The RPD is calculated as follows:

$$RPD = \frac{|X_1 - X_2|}{\overline{X}} \times 100 \tag{1}$$

Where:

 X_1 is the ambient air concentration of a given compound measured in one sample; X_2 is the concentration of the same compound measured during duplicate or replicate analysis; and

X is the arithmetic mean of X1 and X2.

As this equation shows analyses with low variability have lower RPDs (and better precision), and analyses with high variability have higher RPDs (and poorer precision). The RPD method quality objective for all data from the NMP is 25 percent. The replicate data show very good precision with a few outliers present. As shown in Table 7, the overall compound by compound average shows very good precision for replicate analyses at 5.82 percent.

Site ID	# of Duplicates	Median (RPD)	Average (RPD)	Percent Standard Deviation

Bountiful, UT	12	0%	5%	9%
Average	11	4%	6%	6%

The duplicate data show method precision that is not as consistent as the replicate analyses. Results outside the 25% RPD objective can be grouped into two sets. Results with few detectable results show high average but low median results. Other sites show one set of duplicates with high RPD which skews the average RPD above the quality objective. For example, San Juan, Puerto Rico presents a high average of 47 percent, but the median is acceptable at 14 percent. Three duplicate sets were taken and only one of those failed, causing the average to exceed the acceptable limit. Bountiful, UT, Peterson, NJ (site 2), and Grand Junction, CO had similar instances. Other factors, such as unknown sampler/operator errors or canister variance, are possible explanations for high average RPD results. Table 8 presents the overall data average results at 32%, which is slightly over the 25% target.

	# of	Median	Average	Percent Standard

SUMMARY

ERG has determined that Method TO-11A results for acrolein show a significant negative bias. ERG's audit recovery and stability testing demonstrate acceptable results using Method TO-15 for the analysis of acrolein. Comparison to Method TO-11A, demonstrated the acceptable recovery of Method TO-15 analysis using Gas Chromatography/Mass Spectrometry/Selected Ion Monitoring (GC/MS/SIM) for analysis of real field samples for acrolein.

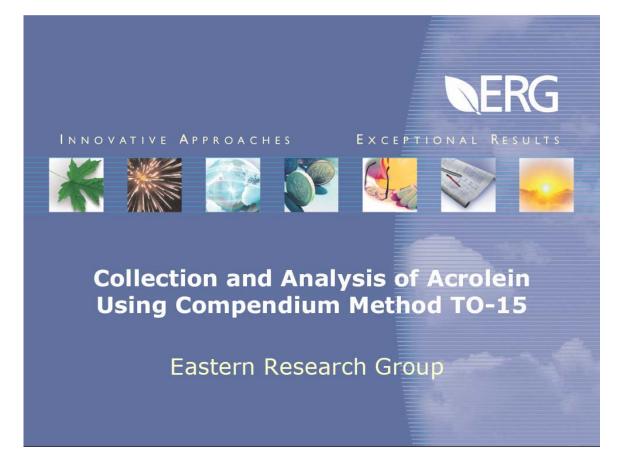

ACKNOWLEDGMENTS

The authors would like to express their appreciation for the hard work and dedication shown by the U.S. EPA, OAQPS staff and Eastern Research Group's laboratory.

Introduction

- Acrolein is listed as one of the core NATTS compounds
- Because of its reactivity, acrolein in ambient air samples presents an analytical challenge
- Penetrates biological membranes, strong dermal irritant, inhalation irritant and possible human carcinogen
- Cancer Risk level 0.018 µg/m³

Possible Active Methods of Acrolein Determination

- Air samples collected on Dinitrophenylhydrazine (DNPH) cartridges, analyzed by Method TO-11A on an HPLC
- Air samples collected in stainless steel canisters, analyzed by Method TO-15 on a GC/MS SIM

3

4

Acrolein Determination by Method TO-11A

- Method TO-11A is based on a specific reaction of organic carbonyls with the DNPH on the sample cartridges in the presence of a strong acid
- Samples are extracted within 2 weeks of sampling
- Extracts are analyzed within 30 days of sample preparation

Potential Problems with Method TO-11A for Acrolein

- Acrolein appears to break down on the DNPH cartridge to form a second derivative peak after sampling
- The second peak coelutes with a Method TO-11A target peak

Method Development – Method TO-11A

5

- Simulated "real world" conditions by using a gaseous blend of carbonyls
- Blended a 100 ppv ±10% gas with clean humidified air to a nominal concentration of 5.92 ppbv
- Collected duplicate samples through a carbonyl sampler and analyzed by Method TO-11A adding the two separate acrolein peaks

Acrolein Recovery using TO-11A (Gaseous Standard)

	Acrolein ^a (two peaks		
Sample	Conc. Recovered (ppbv)	Percent Recovery	
Sample Run 1 – Primary	2.55	43%	
Sample Run 1 – Duplicate	2.18	37%	
Sample Run 2 – Primary	2.59	44%	
Sample Run 2 – Duplicate	2.33	39%	
Sample Run 3 – Primary	2.47	42%	
Sample Run 3 – Duplicate	2.32	39%	
Mean ± Standard Deviation	2.41 ± 0.16	41% ± 3%	

^a Acrolein nominal concentration is 5.92 ppbv.

Method Development – Method TO-15

- Simulated "real world" conditions by using a gaseous blend of carbonyls
- Blended a 100 ppv ±10% gas with clean humidified air to a nominal concentration of 5.92 ppbv
- Collected duplicate samples through a canister sampler
- Recovered 90% of acrolein following Method TO-15

Acrolein using Method TO-15 (SIM Mode)

- Monitor Ions 55 and 56
- Acceptable calibration from 0.25 ppbv to 15.0 ppbv
- 2006 Method Detection Limit of 0.10 ppbv (0.23 µg/m³)

Stability Study of Acrolein in Canister Samples

- Sixteen acrolein samples were prepared in canisters
- Low and high humidity
- Low and high concentration
- Samples were analyzed on Days 0, 7, 14, 21, 28

Method TO-15 Stability Study – Average RPD

	% RPD

11

Acrolein Initial Stability Study

- Rhode Island Dept of Health Labs reported noticed increase immediately after sampling
- Performed short-term stability study
- Took grab samples on an overpass above a heavily traveled highway
- Recoveries for 1,3-Butadiene is presented also because of its close chemical structure to acrolein
- Canisters with nothing detected held for 1 week with no increase in detection (still not detected).

Method TO-15 Field Sample Results for Acrolein

- 19 Sites from July '05 to July '06
- 1,450 acrolein measurements
- 516 of these were from samples during Hurricane Katrina clean-up
- 54% of the 1,450 were detects
- 1.2% of the 1,450 were under the MDL
- Average concentration was 1.54 μg/m³
- Median concentration was 1.08 μg/m³

ERG

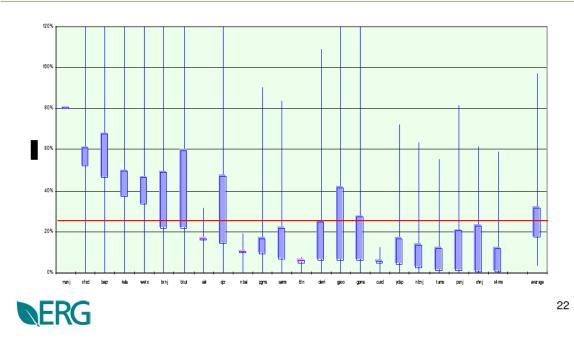

Data Quality Control and Assurance

Compound	ERG (ppbv)	True (ppbv)	% Difference	Uncertainty
Acrolein	1.48	1.21	22.3	± 11.3%
1,3-Butadiene	1.84	1.44	27.8	± 0.2%

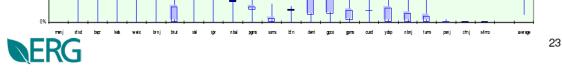

- True value was based on results of 3 analyses performed by Alion/EPA (ORD).
- The percent uncertainty is the coefficient of variation for the three replicate analyses.

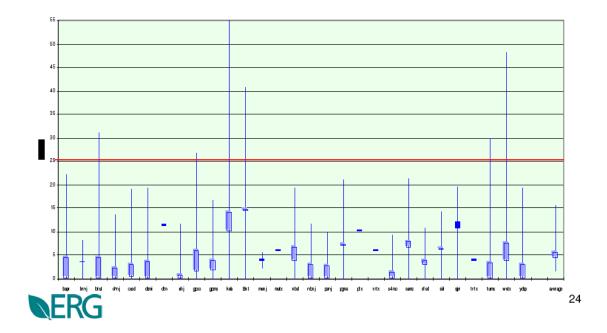

Duplicate Analysis Results (July '05 to June '06)

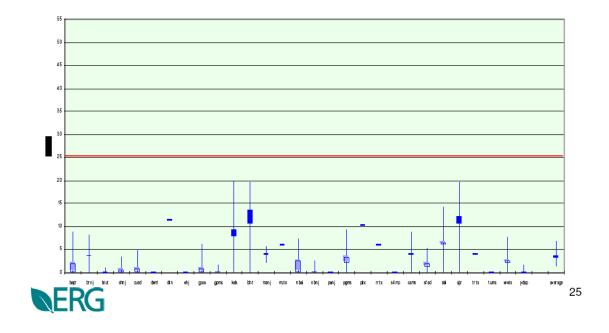

Replicate Analysis Results (July '05 to June '06)

Replicate Analysis without Outliers (July '05 to June '06)

Conclusions

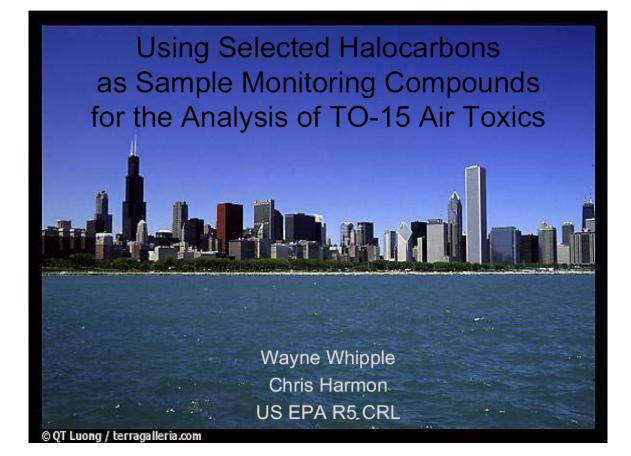

- Higher acrolein recovery using Method TO-15
- Audit, collocate, duplicate, and replicate samples pass NATTS daily quality objectives
- Results from NMP and Katrina are relatively the same and show similar trends
- Need another years data to see if trends are consistent

Outline

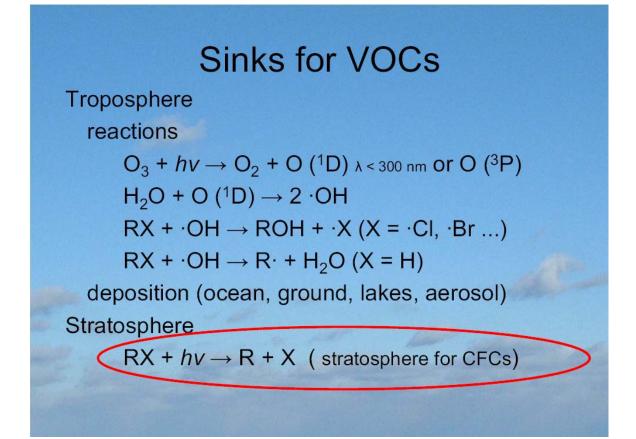

Purpose

- To demonstrate that the use of using selected halocarbons as sample monitoring compounds improves confidence in data
 - Ensure ambient samples are analyzed properly
 - Track the performance of the system
- Theory
 - Source and Sinks of Halocarbons
 - · Production and Usage
 - Montreal Protocol and accords
 - · Lifetime in Atmosphere
 - Global Distribution
 - Background Measurements
- Data
 - Chicago Measurements from October through May 2005
 - · Stability of measurements
 - Histograms
 - Mobile Alabama Study
- Results
 - Use a suite of halocarbons to track each sample for proper analysis
 - Track performance of system and limits of data

Reason why this works

- CFCs are only man made
- Halocarbons persist for a extremely long time in the troposphere
- Were globally banned
 - Proven to cause stratospheric ozone depletion
 - Montreal Protocol
 - discovery of the ozone hole over Antarctica
 - subsequent accords in 1990 and 1992
- They now have consistent concentrations throughout the planet at detectable levels

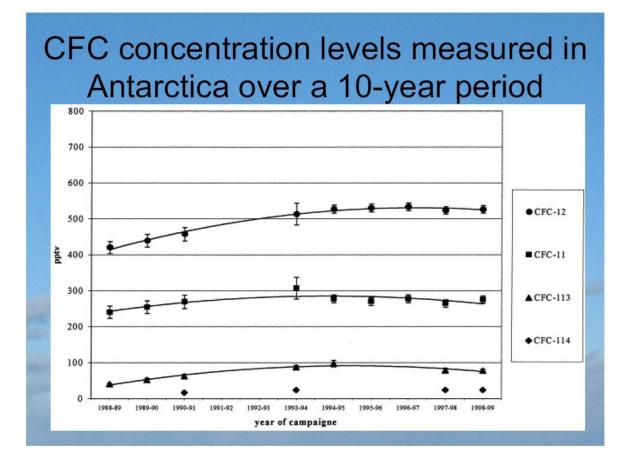

Tropospheric Lifetime of Halocarbons

Halocarbon	Lifetime	Sinks
CCl ₂ F ₂ (F12)	~150 years	Photolysis in stratosphere
CFCl ₃ (F11)	65 years	Photolysis in stratosphere
C ₂ Cl ₃ F ₃ (F113)	~ 100 years	Photolysis in stratosphere
C ₂ Cl ₂ F ₄ (F114)	200 years	Photolysis in stratosphere
CCI ₄	40 years	Photolysis in stratosphere and ocean uptake
CH ₃ CCl ₃ (methylchloroform)	8 years	Reactions with OH

Warnek, Peter; Chemistry of the Natural Atmosphere, 1988 pp 270, 271

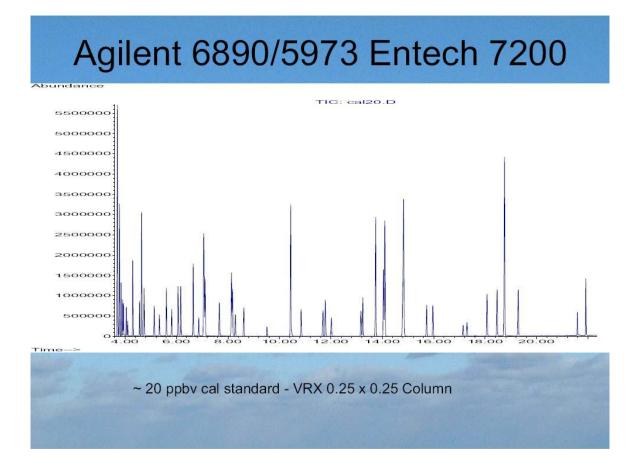

Analysis

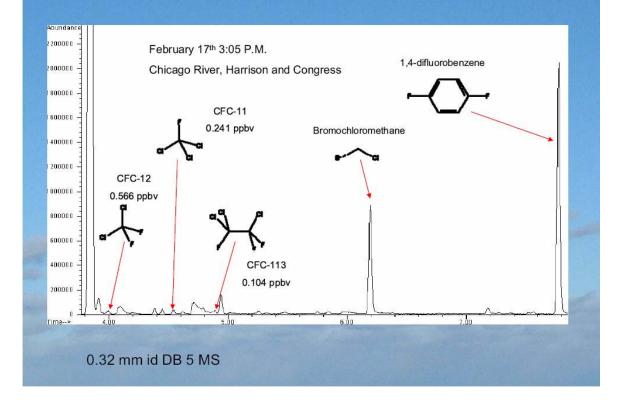

- Samples taken almost every workday from October 2004 through May 2005
- In small park close to major freeways in downtown
- 2.7 L Canisters
- Analyzed using auto sampler and preconcentrator
- Quad GC/MS EI

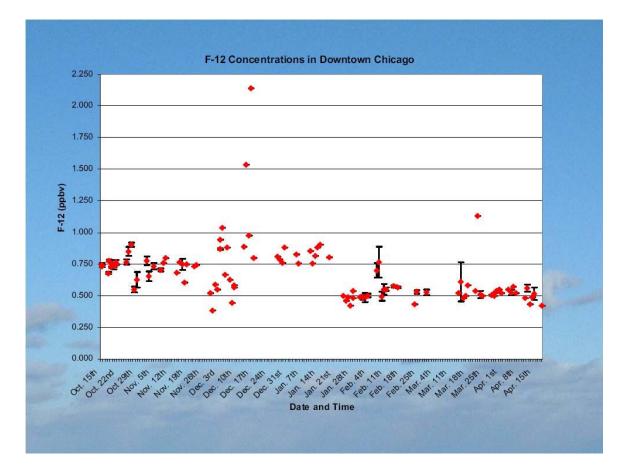

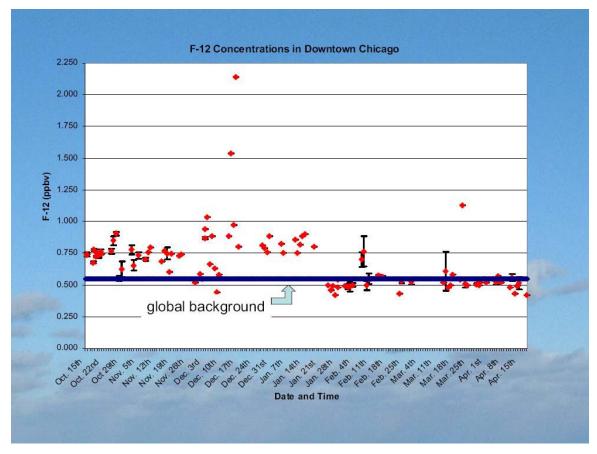

System Monitoring Compounds

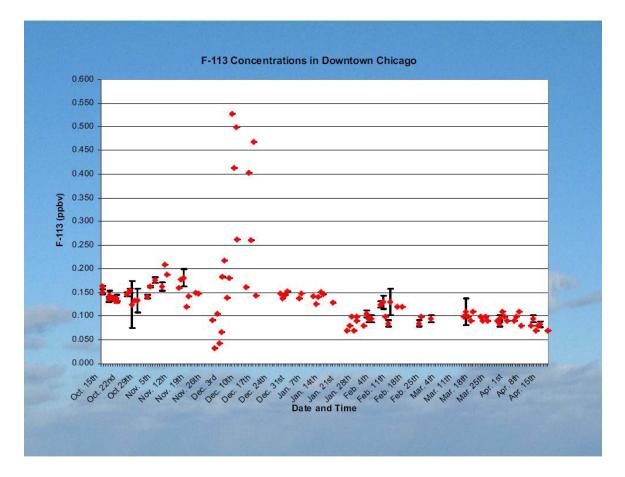

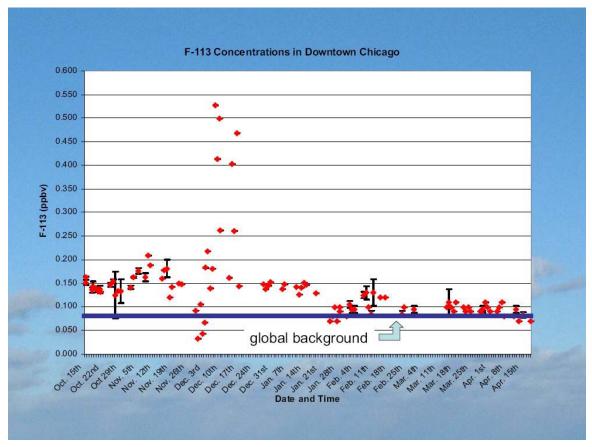

22nd Annual National Environmental Monitoring Conference

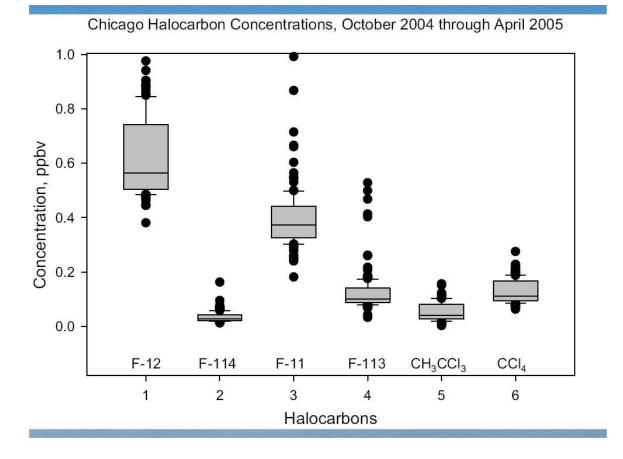

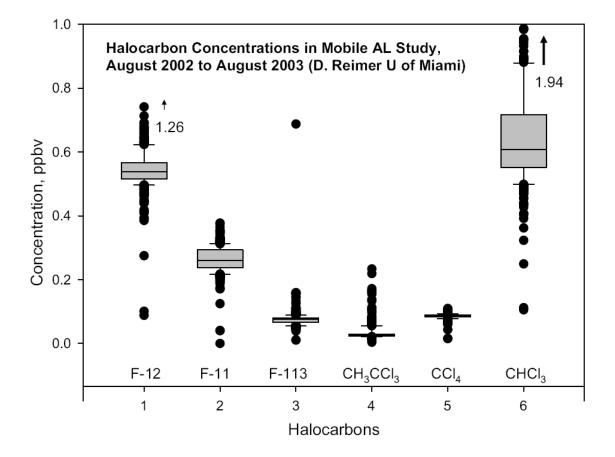

22nd Annual National Environmental Monitoring Conference

Acceptance Limits in the CRL SOP

Compound	Lower Limit Warning Range (ppbv)	Normal Range (ppbv)	Upper Limit Warning Range (ppbv)
Dichorodifluoromethane (F-12)	0.506 - 0.538	0.538 - 0.885	0.885 - 1.060
Dichlorotetrafluoroethane (F-114)	0.010 - 0.015	0.015 - 0.077	0.077 - 0.086
Trichlorofluoromethane (F-11)	0.232 - 0.253	0.253 - 0.589	0.589 - 0.623
1,1,2-Trichloro1,2,2-Trifluoroethene (F-113)	0.074 - 0.080	0.080 - 0.228	0.228 - 0.306
1,1,1-Trichloroethane (methylchloroform)	0.036 - 0.040	0.040 - 0.126	0.126 - 0.159
CCl ₄ (carbon tetrachloride)	0.105 - 0.110	0.110 - 0.214	0.214 - 0.262

• Limits derived from whole data set $\pm 3\sigma$, warning limits set at 2σ of set

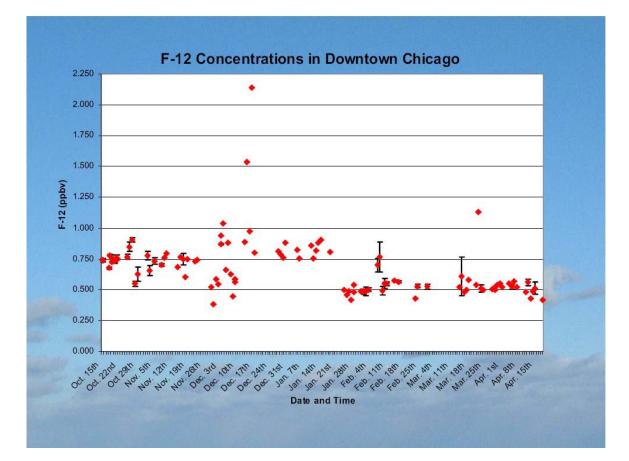

- Three out of the six must be within the acceptance range
- Knowledge of the sample may help if limits are exceeded

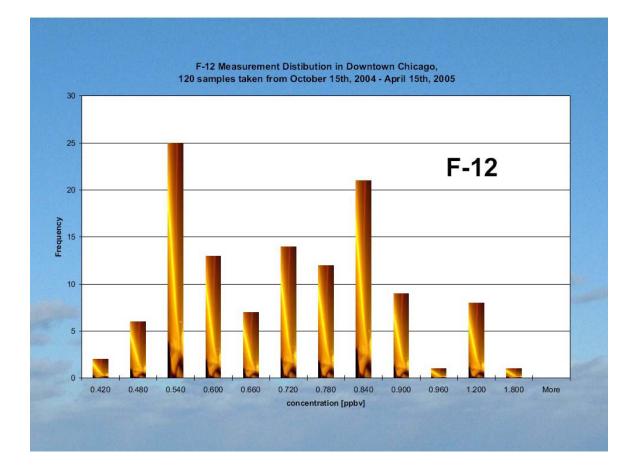

What causes out of limits?

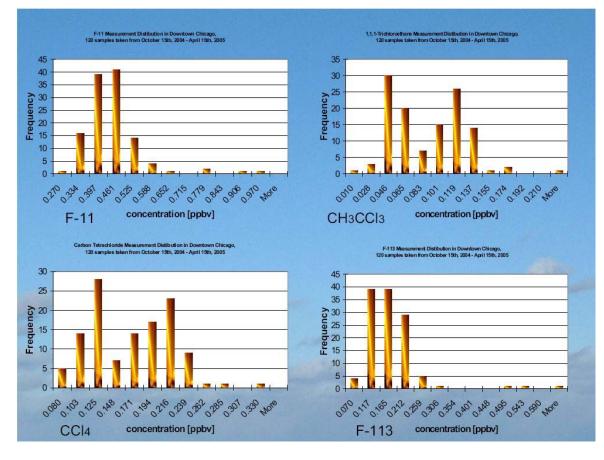

- If compounds are low most causes are:
 - Not enough sample trapped on loop
 - Dilution incorrect
 - Not an ambient sample of tropospheric air
- · If samples are too high most causes are:
 - If all compounds high, dilution error
 - If one or two are high, may be real measurement
 - Sample may still be real measurement if all are high but need to investigate where sample came from

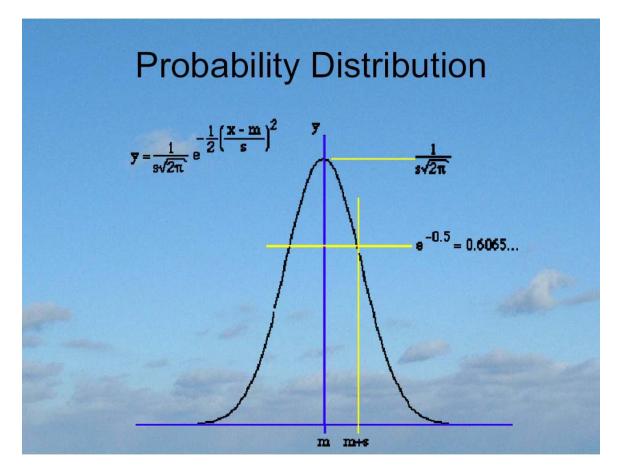

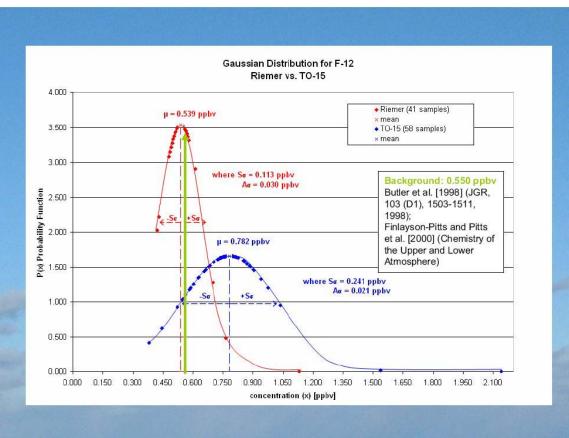

- Accuracy of standards, if only for the exact compounds
- Helps understand the limitations of the analysis
 - Trends in data (correlation analysis)
 - Compliance

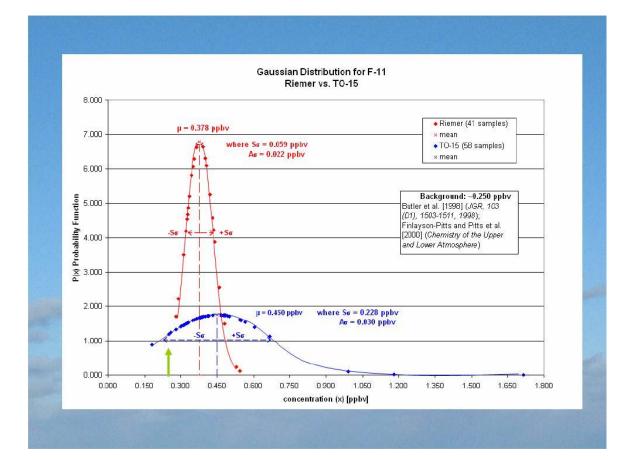

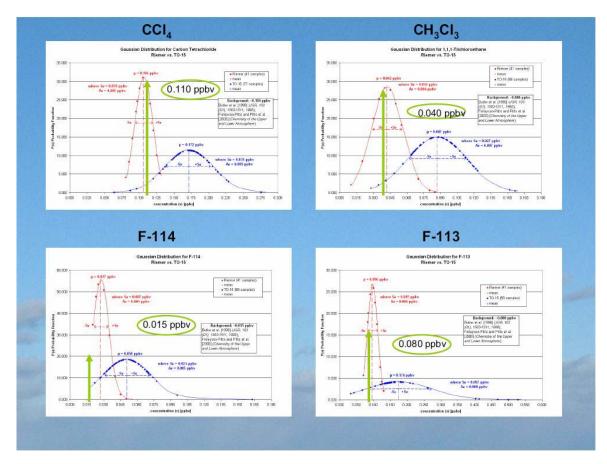

22nd Annual National Environmental Monitoring Conference

Conclusion

 Demonstrated that CFCs and selected halocarbons are consistent throughout most of troposphere

Why they are consistent (sources and sinks)
That they are consistent (global and local data)

 Limits can be set on historical data which are within instrument detection limits, although low.

- F-12 can be diluted 5 times and detectable

 Using these limits has led to understanding both accuracy and precision of data produced by our system

Appreciation

- Region 5 Chicago Regional Laboratory for support
- Chris Harmon for energetic work
- R5 Air Division for financial support for standards and Chris
- LTIG Airheads for help in solving problems
- US Taxpayer (always worth remembering)
- The countries of the world for stopping the production of CFCs, a monumental and unparalleled accomplishment, The world is truly a better and safer place as a result

Collection and Analysis of Hexavalent Chromium in Ambient Air

J. Swift, M. Howell, and D. Tedder

Eastern Research Group, 601 Keystone Park Drive, Suite 700, Morrisville, NC 27560

ABSTRACT

Hexavalent chromium (Cr⁶⁺) is one of the top four pollutants of concern in the EPA National Air Toxics Trends Stations (NATTS) Program. The Environmental Protection Agency (EPA) worked in conjunction with Eastern Research Group (ERG) to improve the California Air Resource Board (CARB) Method 039 for Cr⁶⁺ monitoring. Attempts to sample and analyze Cr⁶⁺ at NATTS with improved sensitivity uncovered challenges in the sampling procedures. Issues with background contamination on filters and stability of field samples were the most important contributors to bias and imprecision. Different filters and filter preparations were studied to minimize background Cr⁶⁺ on filters. A standardized method for media preparation and storage will be discussed. A stability study was performed was performed to determine the best storage conditions to maintain Cr⁶⁺ stability with less than 30 Relative Percent Difference (RPD). The stability of Cr⁶⁺ was also evaluated using collocated samplers with spiked and blank filters. Data, using improvements to the Cr⁶⁺ sampling and analysis procedure for the NATTS, will be presented to show the recent history of Cr⁶⁺ recovery from field samples.

INTRODUCTION

Chromium is a natural constituent of the earth's crust and is present in several oxidation states. Trivalent chromium (Cr^{3^*}) is naturally occurring, environmentally pervasive and a trace element in man and animals. Hexavalent chromium is anthropogenic from a number of commercial and industrial sources. It readily penetrates biological membranes and has been identified as an industrial toxic and cancer substance. Hexavalent chromium is a known inhalation irritant and associated with respiratory cancer. Exposure occurs primarily in the chrome plating and anodizing process, and emissions from chromate treated cooling towers.

METHOD DEVELOPMENT

Previous sampling and analysis studies for Cr^{**} at NATTS have shown a variety of issues including filter contamination and storage stability issues. High filter background concentrations are due to manufacturing processes or contamination in storage. Background contamination results in small differences between measured and blank values, which make data interpretation at low concentrations less confident.

Determining the Sampling Media

Four types of filter media were examined to determine which performed best in terms of background contamination and stability. These filters were prepared using the standard CARB Standard Operating Procedure (SOP) 039 to determine if the chromium leaching off the filters at ambient temperatures would cause contamination. The filters used in this study were:

- Cellulose;
- Binderless Quartz;
- Teflon[®]; and
- Polyvinyl Chloride (PVC).

The results of this study show that the best media is the cellulose filters. The Teflon[®] filter results are questionable because the coating solution does not adhere to these filters. The results for all of the filters are presented in Table 1 below.

	Filter Media Concentrations (total ng)				
Sample Name	Cellulose	Binderless Quartz	PVC	Teflon®	
Day 0 - 1	Not Detected	8.42	2.43	0.320	
Day 0 – 2	Not Detected	6.95	2.03	0.370	
Day 0 – 3	Not Detected	8.22	3.00	0.400	
Day 6 – 1	Not Available	21.91	Not Available	Not Available	
Day 6 – 2	Not Available	47.72	Not Available	Not Available	
Day 6 – 3	Not Available	28.33	Not Available	Not Available	
Day 12 – 1	1.44	Not needed	15.9	0.430	
Day 12 - 2	1.12	Not needed	14.6	ND	
Day 12 - 3	0.760	Not needed	14.4	ND	

Table 1: Chromium Filter Background Contamination - Assessing the Filter Media

ERG treated the cellulose filters selected from initial evaluation of filter media in an attempt to reduce the background below the detection limit of the analysis method. Filters were cleaned with nitric acid to remove hexavalent chromium prior to filter preparation before sampling. Once cleaned, hexavalent chromium was not detected on any unspiked filters. Recovery on spiked filters was from 92 to 100 percent. Based on these results, the acid washed filters are determined to have no associated chromium contamination.

Temporal Stability Study

A temporal study was performed on cellulose and Teflon filters because of the low recovery of background Cr⁶⁺ in the background contamination study. To determine if the preferred filter preparation method would interfere with recovery of Cr⁶⁺ samples, 32 bicarbonate coated cellulose and 32 Teflon filters were prepared and spiked. All filters were spiked with 2.5 total ng⁶⁺ and placed on the laboratory countertop. The experimental design for each filter media included:

 Four spiked filters were analyzed the day they were spiked and four were placed in the freezer.

- Four spiked filters were analyzed the day after spiking (Day 2) and four were placed in the freezer.
- Four spiked filters were analyzed two days after spiking (Day 3) and four were placed in the freezer.
- Four spiked filters were analyzed three days after spiking (Day 4) and four were placed in the freezer.

Table 2 shows the spiked filter results.

	Cellulose Filters		Teflon	Filters	
Spiked	Average Concentration	<u> </u>		Percent	
Samples	(total ng)	Recovery	Concentration (total ng)	Recovery	
Stored at Ro	om Temperature				
Day 1	2.21	$96.03 \pm 4\%$	2.05	$88.93 \pm 5\%$	
Day 2	1.84	$80.14 \pm 8\%$	2.25	97.83 ± 6%	
Day 3	1.64	71.2 ± 8%	2.27	98.8 ± 35%	
Day 4	1.04	$36.1 \pm 21\%$	2.53	$110 \pm 3\%$	
Stored at -18	8°C				
Day 1	1.72	74.9 ± 8%	NA	NA	
Day 2	1.71	74.2 ± 9%	NA	NA	
Day 3	1.32	57.2 ± 3%	2.46	$108 \pm 8\%$	
Day 4	1.13	$49.2 \pm 14\%$	NA	NA	
Blanks	ND	NA	ND	NA	

Table 2: Cr Filter Stability Study

One of the purposes of this study is to determine whether it is feasible to have the filters stored in the field for more than one day after sampling. The cellulose filters stored at room temperature had a significantly reduced recovery from 96 percent on Day 1 to 36 percent on Day 4. The recoveries for the Teflon filters stored at room temperature varied from Day 1 to Day 4 by approximately 15 percent. Similarly, the results for the cellulose filters that were stored at -18°C before analysis ranged from 75 percent on Day 1 to 49 percent on Day 4. Because only one set of Teflon filters was frozen for the stability study, limited data is available for conclusions; however, the recovery for Day 3 is 108 percent. This study shows that the cellulose filters would need to be recovered within 1 day to determine the best recovery, whereas the Teflon filter could be recovered up to 4 days without any significant loss.

Interfering Element Check

Possible interfering compounds were added to the filters and to determine if there were any positive or negative interference when analyzing for Cr^{6*} . All filters were spiked with 10 total ng of Cr^{3*} . Four separate sets of filters were spiked with 10 total ng of Cr^{3*} , Fe, and Mg. All

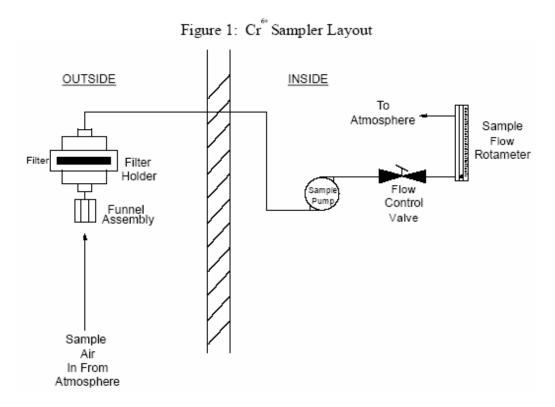

recoveries were within 95.3% \pm 13%, indicating that these elements do not pose any interference for the analysis of Cr⁶⁺.

Method Validation

Field studies were performed to validate the filter preparation and storage study determined acceptable under laboratory conditions.

Cr Sampling Study

A hexavalent chromium sample is collected by pulling ambient air through the prepared filter at a known flow rate for a period of 24 hours. The hexavalent chromium sampling system is designed to automatically perform a 24-hour filter collection and is automated using a digital timer to initiate sample collection at a flow rate of 15 Lpm. The prepared filter assembly is attached to the inlet of the probe, and the funnel is attached to the inlet of the filter assembly. At the end of the 24-hour collection period, the filter assembly containing the exposed filter is removed from the sampler. The Teflon rod stock plugs are reinserted into the inlet and outlet. Figure 1 presents a standard Cr6+ sampling layout.

To validate the preparation and stability of the cellulose and Teflon filters, a sampling study was performed. The sampling site chosen for the study included collocated samplers loaded with either spiked or unspiked filters. For the initial study, each sample sets collected the following cellulose filters:

- One filter unspiked. (Background Sample)
- One filter spiked at 2.5 total ng. Total spiked amount in a 21.6 m³ sample is 0.12 ng/m³. This value is 10 times the current detection limit, but is assumed an appropriate average result from samples collected in the field. (Spike)
- One trip blank (stored in cooler during sampling period). (Trip Blank)
- One filter spiked at 2.5 total ng and left in the filter container. This filter was stored in the freezer while the samples were taken to the field. It was taken out of the freezer immediately before analysis. (Matrix Spike)

All samples were analyzed the day after collection. The results are presented in Table 3 below. All passive and trip blank samples had no detectable hexavalent chromium. The recoveries of spiked samples are slightly better during cold, wet days.

	Conditions					
Sample Set	Sample Volume (m ³)	Humidity	Temperature	Comments	RPD	% Recovery
1		88%	48.8°F		28	72%

Table 3: Ambient Monitoring Study - Cellulose Filters

NOTE: Results listed in **bold** are outside the required relative percent difference (RPD) of 25%. MS = Matrix Spike

The cellulose filters showed varying recoveries on the samples taken. Two of the 8 spiked filters recovered under 70%, with a total average recovery at 80.4%. A comparison study was performed to reproduce the sampling completed on the cellulose filters. This study is presented in Table 4 and is described below:

- Teflon Set 1 through 3 followed same procedures as the cellulose study (spiked at 2.5 total ng),
- Teflon Set 4 through 7 collected using a lower flow rate at 8 L/min (spiked at 2.5 total ng for 4 and 5, 5.0 total ng for 6 and 7),
- Teflon Set 8 and 9 collected at 15 L/min with a particulate filter before the spiked filter (spiked at 2.5 and 5.0 total ng, respectively),

 Teflon Set 10 and 11 collected using an ozone scrubber cartridge (used for TO-11A sampling) that would take out ozone as well as particulate (spiked at 2.5 total ng).

Sample Set	Setup	RPD	% Recovery
Teflon Set 1	Charles 1 and the set 15	24	76%
Teflon Set 2	Standard conditions at 15 L/min	64	36%
Teflon Set 3		4.0	96%
Teflon Set 4		1.2	101%
Teflon Set 5	Flow at 8 L/min	83	17%
Teflon Set 6	Flow at 8 L/IIIII	9.0	109%
Teflon Set 7		60	41%
Teflon Set 8	Collected a particulate filter	1.9	98%
Teflon Set 9	before spiked filter	5.6	94%
Teflon Set 10	Collected using an ozone	13	113%
Teflon Set 11	scrubber before spiked filter	6.3	94%

Table 4: Spiked Teflon Filter Study (with rough polypropylene support)

NOTE: Results listed in **bold** are outside the required relative percent difference (RPD) of 25%. The Teflon also showed varying recoveries. Three of the 11 spiked filters recovered under 70%, with a total averaged recovery at 79.5%. This indicated a close comparison of the Teflon to the cellulose filter Cr^{α} collection.

In order to distinguish other possible interferants, another set of experiments were preformed:

- Volume Check -the rate of collection was too high by reducing the overall sample volume to 11.5 m³,
- Particulate Check -the particulate reacted with the Cr[®] to reduce it to Cr[®] by having a Teflon filter inline before the spiked filter, and
- Ozone Check ozone reacts to oxidize other agents that could reduce the Cr[®] to Cr[®]. As presented in Table 5, the Cr[®] recovery was not affected by changing any of these parameters

As presented in Table 5, the Crst recovery was not affected by changing any of these parameters (volume, particulate and ozone).

Sample	Spiked in total ng	Results in total ng	Percent Recovery		
Volume Check - colle	ected at 11.5 m ³ (instea	d of standard 21.6 m ³)			
Run 1	2.5	2.53	101%		
Run 2	5.0	5.45	109%		
Particulate Check - co	ollected particulate bef	ore ambient air crossed	spiked filter		
Run 1	2.5	2.45	98.1%		
Run 2	5.0	4.72	94.4%		
Ozone Check – scrubbed ozone and particulate before ambient air crossed spiked filter					
Run 1	2.5	2.82	113%		
Run 2	5.0	4.68	93.7%		

Table 5: Physical Interferants Check for Cr Sampling

Comparison Sampling Using Cellulose and Teflon Filters

The optimal way to confirm the performance using either filter is to collect collocated sets of cellulose and Teflon filters. ERG sent five different NATTS sites the standard cellulose and Teflon filters as a means to evaluate the performance of the Teflon filters. These sites were selected based on recent history of Cr⁵⁺ in their samples. The results are presented in Table 6 below.

Site	Total # of Samples	Similar Results on Cellulose and Teflon (±30% RPD)	Cellulose Concentration Higher (>30% RPD)	Teflon Concentration Higher (>30% RPD)
Boston, MA	3	0%	100%	0%
Detroit, MI	5	20%	80%	0%
Seattle, WA	4	75%	25%	0%
Tampa, FL	5	0%	80%	20%
Washington, DC	4	0%	75%	25%
Average	4	19%	72%	9%

Table 6: Comparison of Cr⁶⁺ Recovery on Cellulose and Teflon Filters

Note: Sampling was conducted from June to August 2005.

This table shows the total number of samples collected at each site and compares the Cr⁶⁺ recoveries of the cellulose to the Teflon filters. For example, the site in Detroit sampled 5 sets of filters (one cellulose and one Teflon filter) during the same sampling period. One of these filter sets had similar recoveries for the cellulose and Teflon filters, and the other 4 filter sets had higher Cr⁶⁺ recoveries with the cellulose filters. The lower recovery on the Teflon filters could be due to other reducing compounds in the ambient air that would convert the Cr⁶⁺ to Cr³⁺. This is prevented from occurring on the cellulose filters because of the sodium bicarbonate coating. In

Seattle, WA, the air stream is being blown from the west, off the Pacific Ocean. Because of the lower interference from mobile and emission sources, the difference between the cellulose and Teflon filters is minimal. The other 4 sites (Boston, Detroit, Tampa, and Washington, DC) are in highly populated areas where these emissions could reduce the Cr^{e} significantly. Based on the results of this sampling study, ERG determined that collection on the acid washed, sodium bicarbonate coated cellulose filters would recover the Cr^{e} more efficiently for real-world ambient samples.

FIELD SAMPLE RESULTS FOR HEXAVALENT CHROMIUM

Twenty-two National Monitoring Program (NMP) sites collected Cr⁶⁺ samples from January 2005 to December 2005. Some monitors were placed near the centers of heavily populated cities (e.g., Chicago, IL and Detroit, MI), while others were placed in moderately populated areas (e.g., Madison, WI and Hazard, KY). Hexavalent Chromium concentrations measured during this time varied significantly from monitoring location to monitoring location. The proximity of the monitoring locations to different emissions sources, especially industrial facilities and heavily traveled roadways, often explains the observed spatial variations in ambient air quality. Table 7 presents the frequency of detects, maximum value, minimum detected value, median, and average.

Site	Frequency of Detects	Maximum Value (ng/m³)	Minimum Value (ng/m ³)	Median (ng/m ³)	Average (ng/m³)

Average	58%	0.168	0.007	0.025	0.034

A total of 1,209 Cr^{fr} measurements were detected at the 22 NMP sites from January 2005 to December 2005. Two hundred and nine of these were taken at three sites during the clean up after Hurricane Katrina. Of the 1,209 Cr^{fr} measurements, 58% of these results were detects and 12% of these concentrations were below the MDL. The average Cr^{fr} concentration was 0.034 ng/m³.

Data from the NMP sites is presented in Figure 2. The highest concentration was taken at Washington, DC, at 1.97 ng/m³. The samples taken for Katrina were collected on a 1-in-1 schedule starting October 10, 2005. Hexavalent chromium results at Katrina monitoring sites were similar or slightly lower than other sites in the program.

Figure 2: Analytical Cr[®] Results for Samples Collected Between January 2005 and December 2005 All Cr6+ results

DATA QUALITY CONTROL AND ASSURANCE

Precision of the analytical and sampling technique was determined using the analysis of collocated sampling episodes. A collocated sample (i.e., a sample collected simultaneously with the primary and collocated sample using separate sampling systems) provides information on the potential for sampling variability. ERG was not able to perform replicate analyses because the final sample instrument injection volume did not allow the replicate analyses. Method spikes were analyzed, however, and give an acceptable range of 80-120% recovery. The collocated results were compiled from sites sampling in the NMP from January 2005 through December 2005.

The collocated data is presented in Relative Percent Difference (RPD). The RPD expresses average concentration differences relative to the average concentrations detected during collocated analyses. The RPD is calculated as follows:

$$RPD = \frac{|X_1 - X_2|}{\bar{X}} \times 100$$
 (1)

Where:

X1 is the ambient air concentration of given compound measured in one sample;

 X_2 is the concentration of the same compound measured during collocated analysis; and X is the arithmetic mean of X_1 and X_2 .

As this equation shows analyses with low variability have lower RPDs (and better precision), and analyses with high variability have higher RPDs (and poorer precision). The RPD method quality objective for all data from the NMP is 25 percent.

Collocated results outside the 25% RPD objective can be grouped into two sets. Results with few detectable results show high average RPD but low median RPD results. Other sites show one set of collocates with high RPD, which skews the average RPD above the quality objective. For example, Seattle, Washington presents a high average of 28 percent, but the median is acceptable at 6.1 percent. Seven collocated sets were taken and only one of those failed, causing the average to exceed the acceptable limit. Table 10 presents the collocated data results.

Site ID	# of Collocates	Median (RPD)	Average (RPD)	Percent Standard Deviation
S. Dekalb Co., GA	3	89.0%	89.0%	6.1%
Austin, TX	1	30.5%	30.5%	0.0%
Detroit, MI	4	20.3%	19.1%	12.6%

Average	5	11.8%	16.9%	16.2%

Table 10: Collocate Statistical Data Results (January 2005 to December 2005)

The overall data average RPD result is 16.9%, which is within the 25% target. The S. Dekalb Co., GA site is a notable exception to this group of results. This location has a sampler that requires the filters to be installed on site instead. The normal practice is to place them in a filter holder under controlled laboratory conditions to prevent Cr^{st} contamination. All of the collocated results from S. Dekalb Co. ranged from 82 to 91% RPD.

CONCLUSIONS

Based on the results of this study, ERG concludes Teflon filters do not collect the Cr^{\bullet} more efficiently then cellulose. Reducing agents in the ambient air seem to be converting the Cr^{\bullet} to T^{\bullet} and the filter media must stabilize and protect the Cr^{\bullet} from these reducing agents. The Teflon filters do not have the buffer coating (sodium bicarbonate) to stabilize the Cr^{\bullet} on the filter when reducing agents, such as acid gases.

ERG laboratory's detection limit for acrolein is 0.012 ng/m' (experimentally determined using 40 CFR, Part 136 procedures) which is lower than the cancer and noncancer health risk threshold concentration. Based on the results of this study, sample collection using the sodium bicarbonate coated cellulose filters is recommended. There are certain preservation procedures that must be followed before acceptable sample results should be reported, including:

- The filters must be acid washed and rinsed before coating them with the sodium bicarbonate to prevent Cr[®] background. Using this method however, does not lengthen the collection or storage hold time.
- All samples must be retrieved from the field one day after the sample has been collected to prevent Cr^{*} negative bias (loss) (up to 20% on the first day).
- All samples must be frozen after collection to reduce the risk of Cr^{*+} loss.

Analysis of sodium bicarbonate coated cellulose filters containing known concentrations of Cr^{**} demonstrated acceptable recoveries, if the samples are recovered as soon as possible after sampling ends.

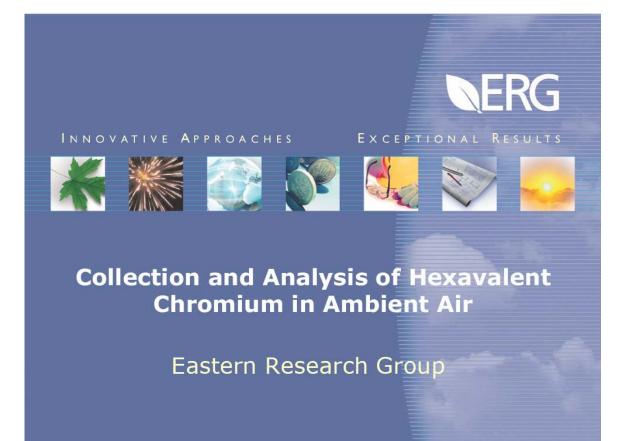

ERG has determined that this modified method shows consistent recovery for $Cr^{\bullet \bullet}$ over time throughout the country. The collocated sample recoveries meet the method quality objectives set by the EPA for the NATTS program, however there does seem to be limitations on sample recovery for loading filters outside of the controlled laboratory conditions.

ACKNOWLEDGMENTS

The authors would like to express their appreciation for the hard work and dedication shown by the U.S. EPA, OAQPS staff and Eastern Research Group's laboratory.

Introduction

- Chromium is present in several oxidation states
- Cr³⁺ is naturally occurring, environmentally pervasive and a trace element in man and animals
- Cr⁶⁺ is anthropogenic from a number of commercial and

industrial sources

Hexavalent Chromium Health Effects

- Penetrates biological membranes
- Identified as an industrial toxic and cancer substance
- Inhalation irritant and associated with respiratory cancer
- Cancer Risk Level 0.084 ng/m³
- Non-Cancer Risk Level 0.00011 ng/m³
- ERG MDL Level 0.011 ng/m³, assuming 21.6 total m³ sampled

21

Conclusions

- Teflon filters do not collect the Cr⁶⁺ more efficiently then cellulose
- Sample collection using sodium bicarbonate coated cellulose filters is recommended
- Filters must be acid washed before coating them with sodium bicarbonate to prevent Cr⁶⁺ background

Conclusions, Cont.

- Samples must be retrieved from the field one day after the sample has been collected to prevent Cr⁶⁺ loss
- Samples must be frozen after collection to reduce the risk of Cr⁶⁺ loss

PASSIVE MONITORING OF GROUND LEVEL OZONE

Matthew, Johnson; United States EPA

Chemically impregnated filters are used to passively monitor ground level ozone, nitrogen dioxide, sulfur dioxide and ammonia in ambient air. Contaminant in air reacts with chemical on the filter to form respective complex. Using Ion Chromatography instrument we can determine the reacted species. This presentation will demonstrate use of Ion Chromatography instruments to monitor and calculate ground level Ozone, Nitrogen dioxide, Sulfur dioxide and Ammonia in ambient air.

 > US ENVIRONMENTAL PROTECTION AGENCY HAS ESTABLISHED NATIONAL AMBIENT AIR QUALITY STANDARD FOR SIX AIR POLLUTANTS;

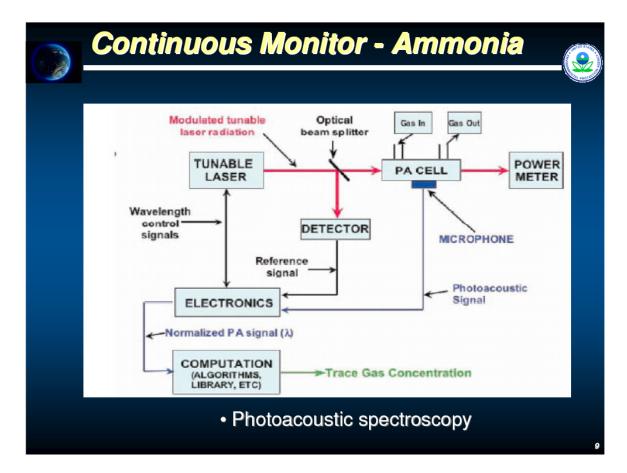

- OZONE
- NITROGEN DIOXIDE
- SULFUR DIOXIDE
- CARDON MONOOXIDE
- LEAD
- RESPIRABLE PARTICULATE MATTER

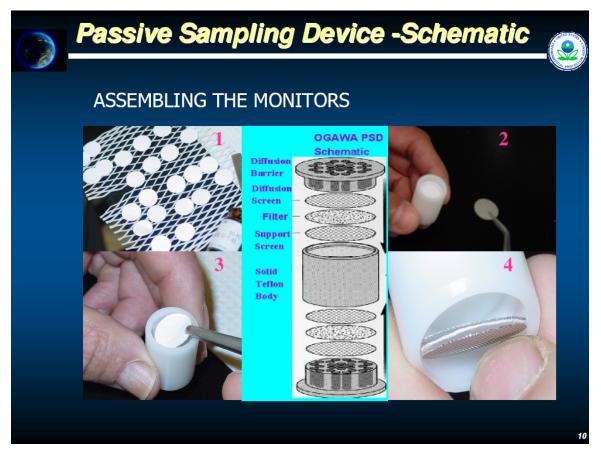

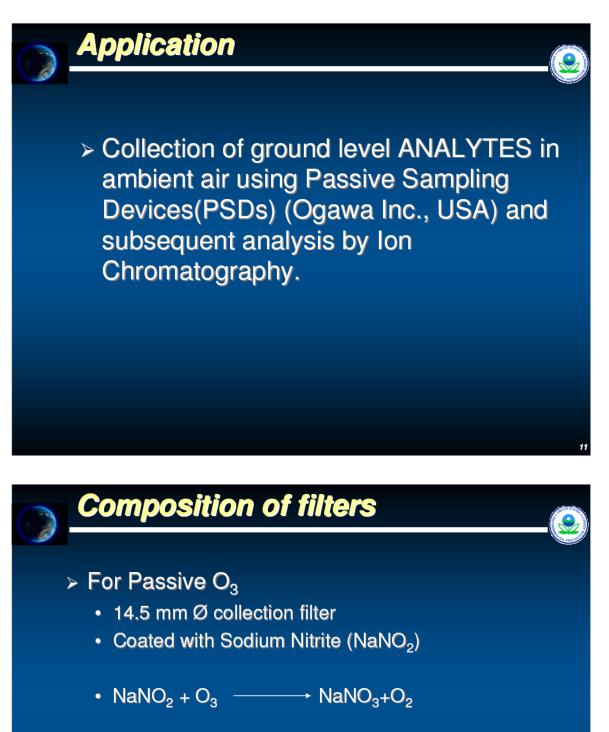

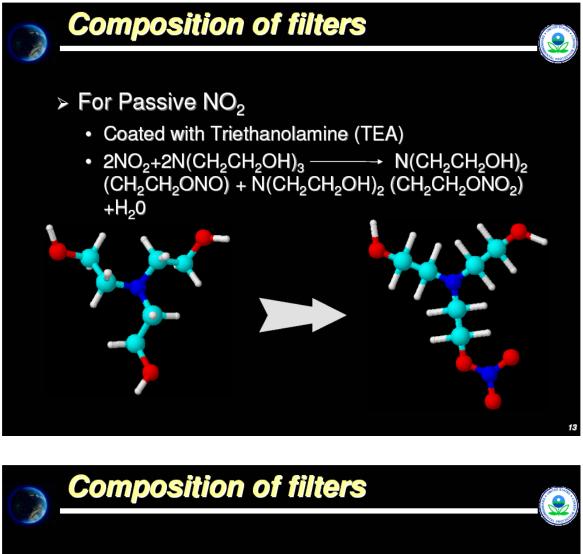

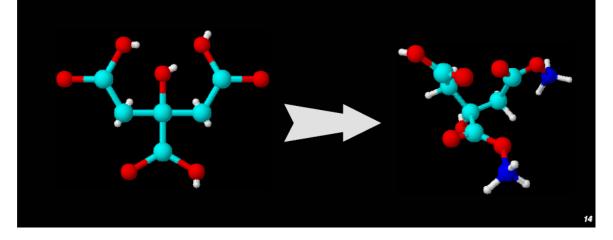

➢ For Passive SO₂

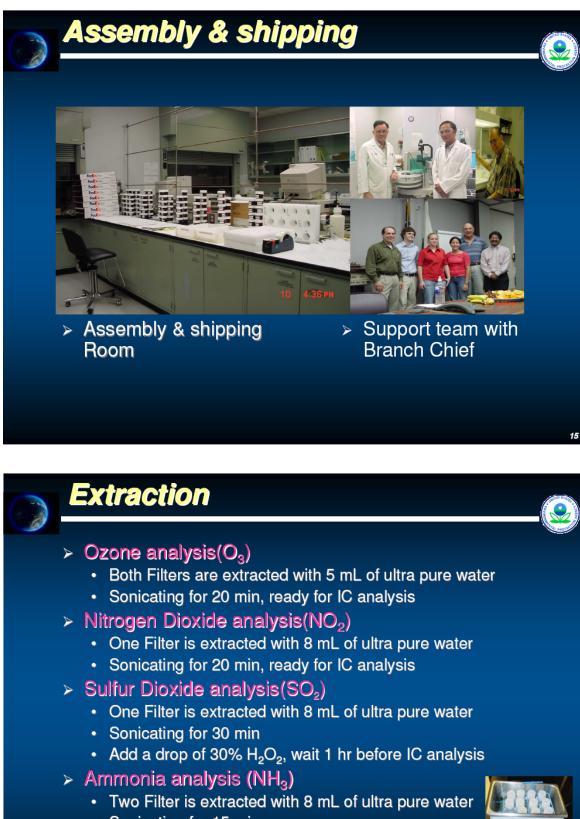

- 14.5 mm Ø collection filter
- Coated with Triethanolamine (TEA)

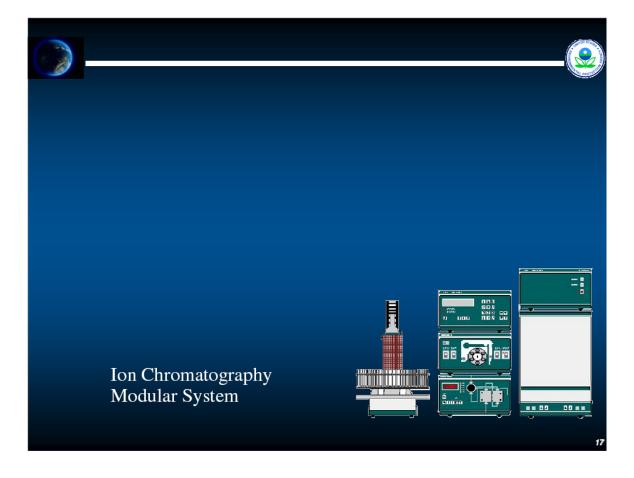

➢ For Passive NH₃

- · Coated with Citric Acid
- $NH_{3}+H_{3}C_{6}H_{5}O_{7} \longrightarrow NH_{4}H_{2}C_{6}H_{5}O_{7} / (NH_{4})_{2}HC_{6}H_{5}O_{7} / (NH_{4})_{3}C_{6}H_{5}O_{7}$

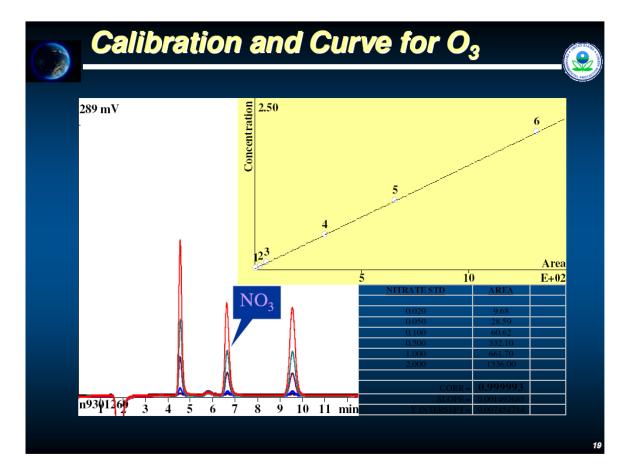

- Sonicating for 15 min
- * occasional shaking at all steps is required

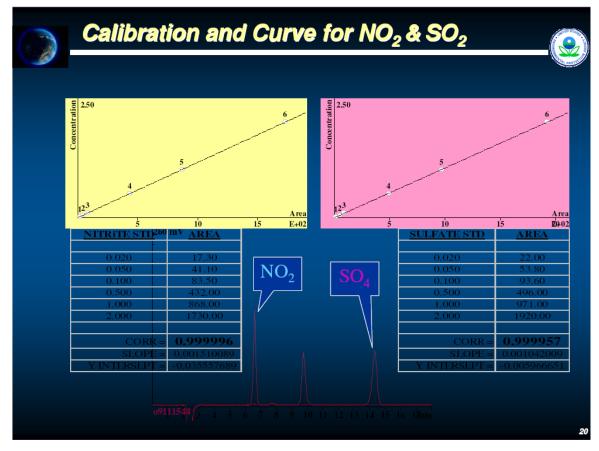

Experimental Conditions

> For O_3 , NO_2 and SO_2

- Metrohm Modular IC system
 - Eluent: 3.5 mM sodium carbonate
 - Sample loop size: 25 μL
 - Flow rate: 0.7 mL/min
 - Column
 - Analytical Column: MetroSep ASUPP 5
 (4mm x 100 mm)
 - Guard: RP guard disk

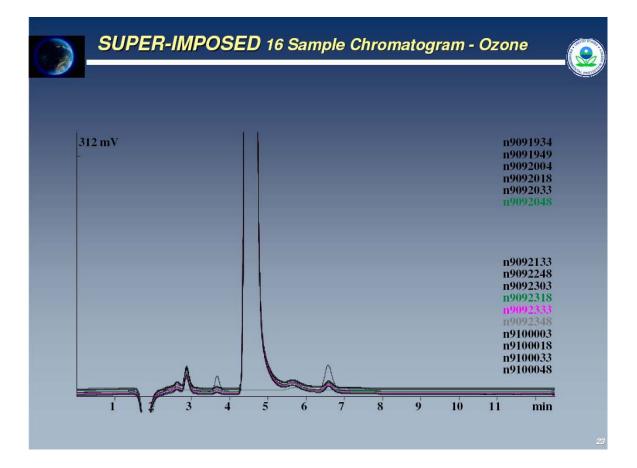

Sampling Site Locations

 The sites were located in a variety of areas including high populated areas, downwind rural areas, and different areas of complex terrain (e.g. on mesas/mountains or in valleys)

Calculations for Ozone

O_3 concentration (ppb) = ConNO₃(ug/mL)* X

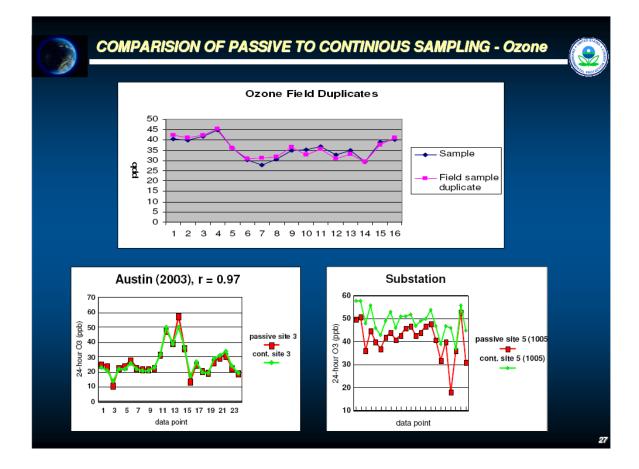

- (example 0.7104 ug NO₃/ml) for 24 hr sampling
 - The ozone concentration is calculated from the following equation:
 - 0.7104 ug NO₃/ml*5 ml
 - 3.552 ug
 - Sampling rate = 21.8ml/min
 - $O_3 \text{ ppm}=$ (3.552 ug NO3/ (21.8ml/min * 1440) *1u mole NO₃/62 ug NO₃ * 1 u mole O₃/1 u mole NO₃ *24.5ul O₃/1 u mole O₃ * 10⁻⁶ (m³) O₃/1000 ul O₃ * 1/0.03139 m³)
 - 0.045ppm O₃

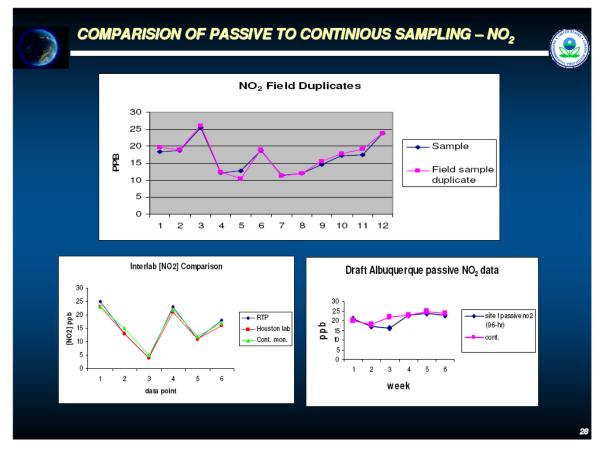

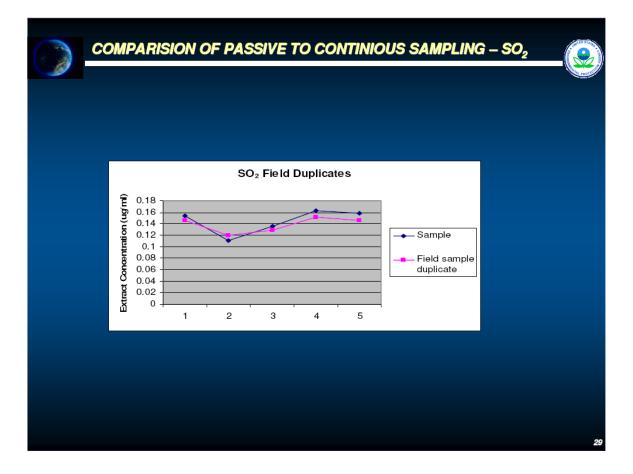

> PPB SO₂=(α_{NO2})*ng SO₄ =(α_{NO2})*ugSO₄ *1000 ug SO₄ is determined by IC

 α_{SO2} =1000/(0.677*P*RH)+(2.009*T)+89.8 where P={2P_N/(P_T+P_N)}^{2/3} At 20 °C the value of α^{SO2} = 39

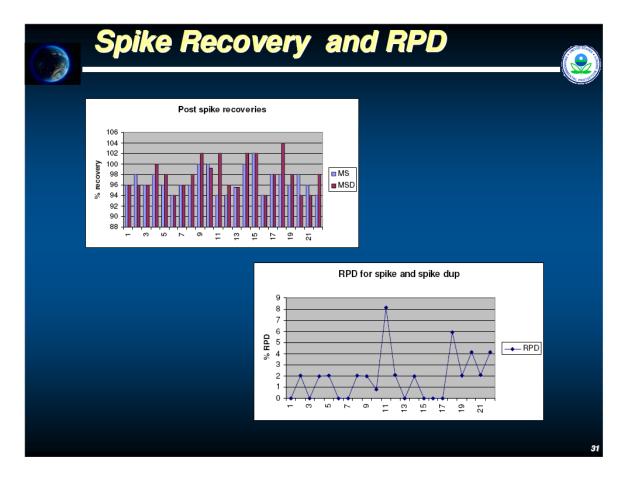

T=Ambient temperature in $^{\circ}$ C RH= Relative humidity P_N=17.535 (water vapor pressure @20 $^{\circ}$ C) P_T=vapor pressure at ambient temperature

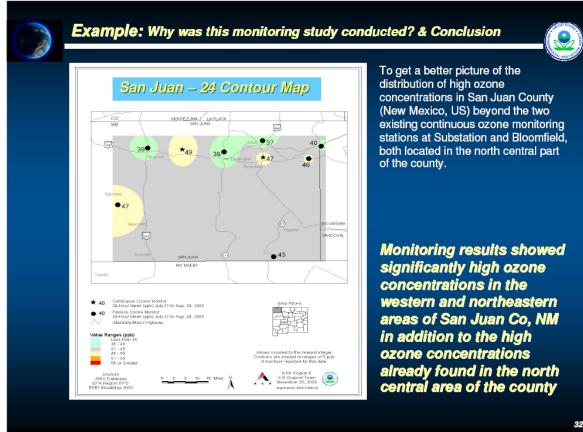

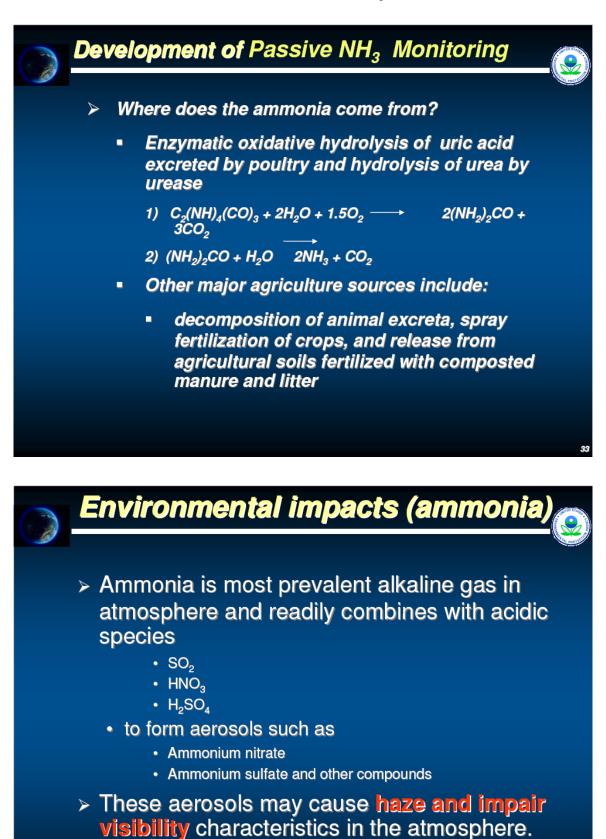

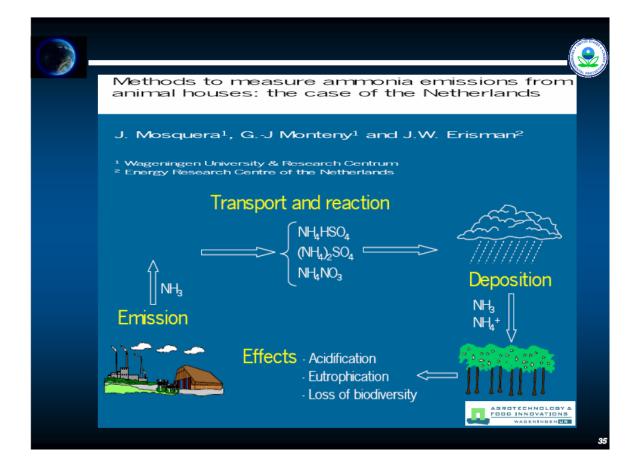

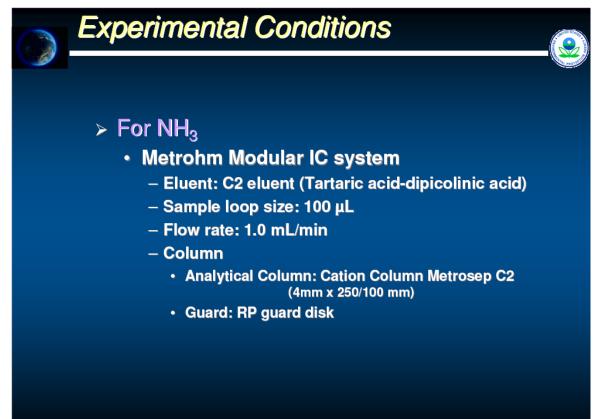

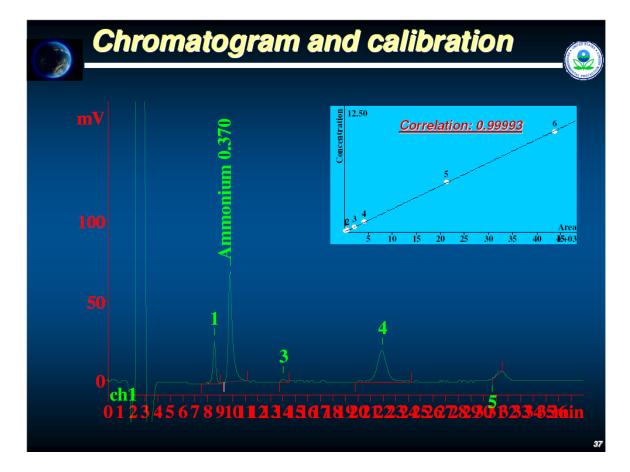

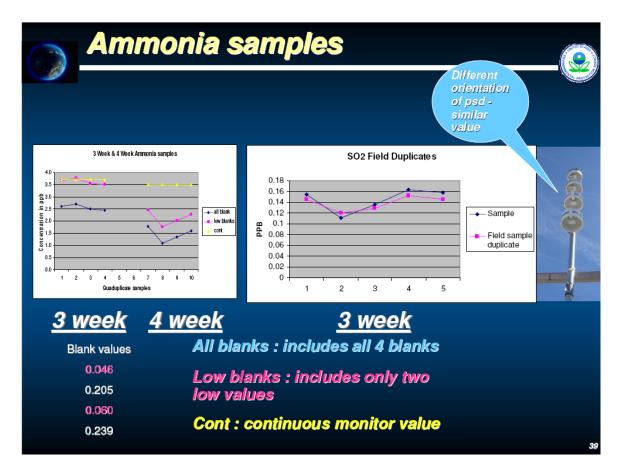

Concentration calculation for NH₃

- > NH_3 concentration (ppb) = (ConNH_3(ng)* α ^{NH}₃)/t
 - where :
 - ConNH₃ = the ammonia quantity (in ng)
 - α^{NH_3} is the ppb concentration conversion coefficients (ppb min/ng).
 - $-\alpha^{\rm NH}{}_{3}=43.8$
 - t is sample collection time in minutes

Conclusions

- Benefits of passive sampling
 - · Very easy to use
 - No power required
 - Ogawa Sampler is reusable countless times
 - Same sampler is used for diffrent gases.
 - Where cost is an issue passive sampling provides an inexpensive alternative to continuous sampling
 - Usually used for 24-hour or longer sampling, although for ozone it can be successfully used for time intervals as short as 8 hours
 - Can provide credible monitoring data to help fill in data gaps and to screen new areas, including remote rural areas.

ENHANCEMENTS OF EPA METHOD 535

Krol, Jim Sr.; Waters Corporation

EPA Method 535, ver 1.1, authored in April 2005 discusses a method limitation with the identification and quantification of alachor ESA from acetochor ESA. These analytes are structurally similar having the same molecular weight and MSMS transitions, and requires chromatographic resolution prior to MSMS. Because of this limitation, 2 possible candidates are within the same retention time window, and the identification of these analytes must be manually checked; a time consuming task.

The method calls for an ammonium acetate/methanol gradient using a 5 μ m, 2.1 x 100 mm, dC18 column at 60°C. These chromatographic conditions are optimize for efficiency necessary to resolve alachlor EAS from acetochlor EAS. However, the trade off is high backpressure due to MeOH viscosity. Because of stated MS suppression effects of sample TOC on analyte response, this chromatographic mobile phase cannot be modified, but the column selectivity can be changed.

This presentation will discuss the applicability of other LC column chemistries to achieve the required resolution. Concurrently, other mobile phase types may improve resolution and MSMS sensitivity without sacrificing TOC suppression.

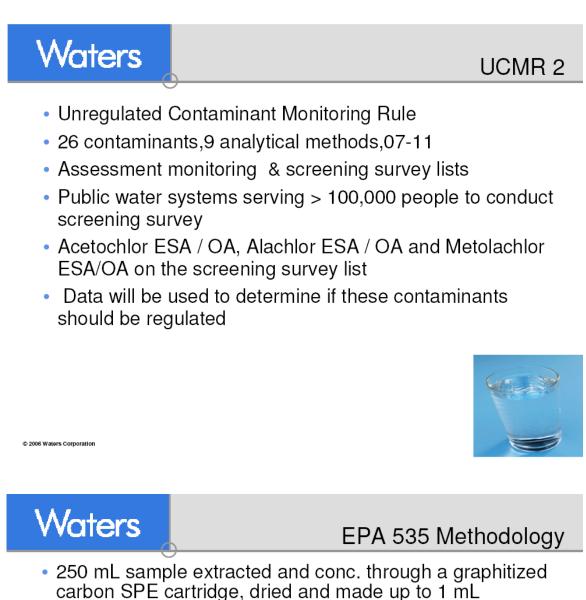

Waters Chloroacetanilide / Acetamide Herbicides

 U.S. Registered Alachlor, Acetochlor, Metolachlor, Propachlor, Flufenacet and Dimethenamid

- Control of broadleaf & annual grasses on crops
- ESA (Ethane Sulfonic Acid) & OA (Oxanilic Acid) Metabolites
- Metabolites are more water soluble and have increased mobility than parent herbicide
- USGS reported higher conc. & occurrence of metabolites than parent compounds in ground & surface water

- Sample injected on C₁₈ column at 65^oC and analyzed by LC/MS/MS, negative ion mode, multiple reaction monitoring (MRM)
- Mobile phase 5 mM ammonium acetate & methanol
- Concentration determined by use of chromatographic internal standard calibration
- Waters Alliance HPLC or Waters ACQUITY UPLC with Quattro Micro API Tandem Quadropole Mass Spectrometer used in this study

Waters

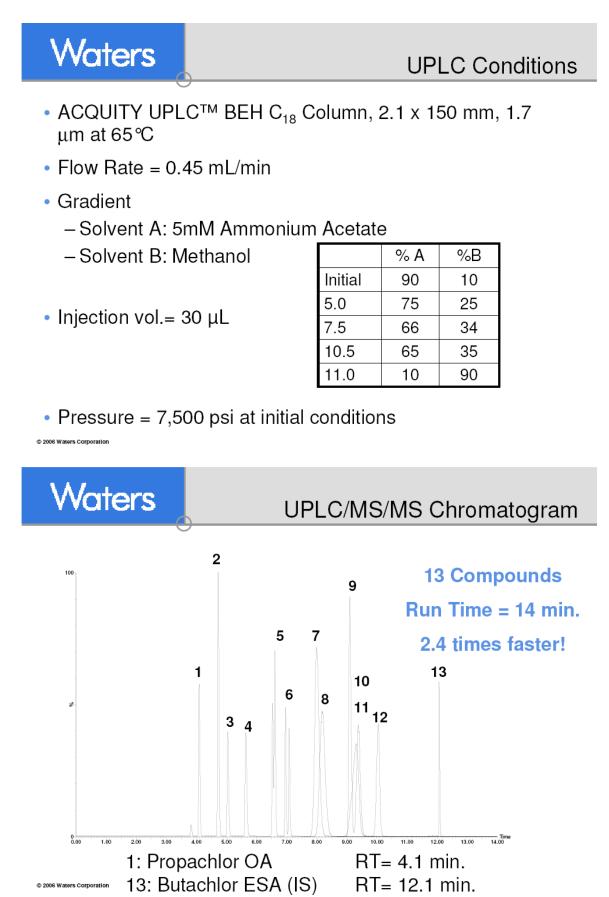

Enhancing the Method

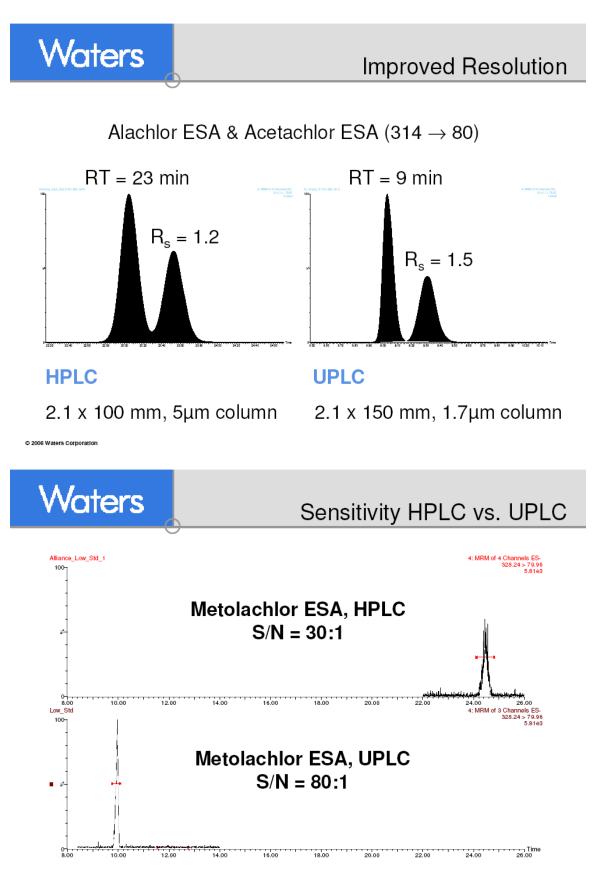

- Increase throughput
 - EPA Mth. HPLC / Tandem Quad runtime = 35 min.
 - EPA Mth. HPLC / Ion Trap runtime = 60 min.
- Resolution

- Alachlor ESA and Acetachlor ESA are structural isomers, same MRM channel; 314 \rightarrow 80
- Required resolution, Rs > 1.0

Linearity

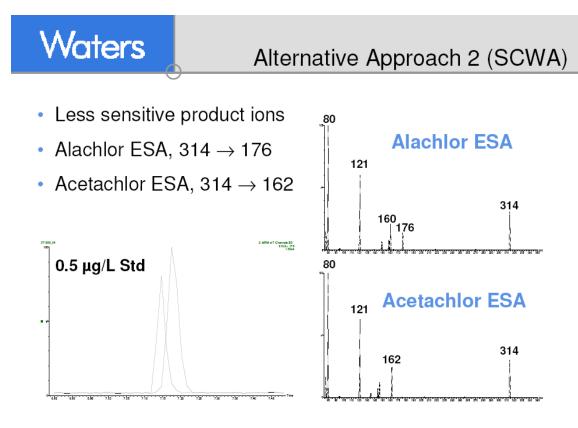

- Calibration curves were constructed using an internal standard method
- Concentration of standards was 0.05 $\mu g/L$ to 1.00 $\mu g/L$ for 250 mL of extracted sample
- Correlation coefficients > 0.997 were obtained for all 6 metabolites on UCMR2 list
- Processing carried out using QuanLynx software

Notes: 250 mL of sample extracted using an automated system

Detection Limits determined by analyzing 7 replicates

Advantages of UPLC for EPA Method 535 Include:

- Increased Throughput
 - EPA method runtimes reported are up to 60 mins, runtimes of 9 minutes were achieved by UPLC
- Better Resolution
 - Improved Rs values for Alachlor ESA and Acetachlor ESA
- Sensitivity
 - \geq 2X increase in sensitivity over HPLC
 - Increase in sensitivity allowed use of less sensitive product ions for Alachlor ESA and Acetachlor ESA

STIR BAR SORPTIVE EXTRACTION (SBSE) SAMPLE PREPARATION FOR AQUEOUS ENVIRONMENTAL SAMPLES: AN OVERVIEW

Pfannkoch, E. A.; Stuff, J. R.; and Whitecavage, J. A. – GERSTEL, Inc.

The determination of volatile and semivolatile analytes in aqueous solutions using stir bar sorptive extraction (SBSE) as the extraction step is gaining acceptance in a wide variety of application areas including water and wastewater analysis, foods and beverages, and other consumer products. SBSE uses a high capacity polydimethylsiloxane (PDMS) phase on a stir bar to simultaneously stir and concentrate nonpolar analytes from polar matrices, eliminating organic solvent extraction. Analytes are transferred to the GC by thermal desorption, typically achieving sub-ppb detection limits from sample sizes of 20mL or less.

This presentation will provide an overview of SBSE method optimization and illustrate the technique with examples including semivolatile organics (EPA Method 8270), PAH's, pesticides, and other applications of environmental interest.

Stir Bar Sorptive Extraction Environmental Applications

Trends in Residue Analysis

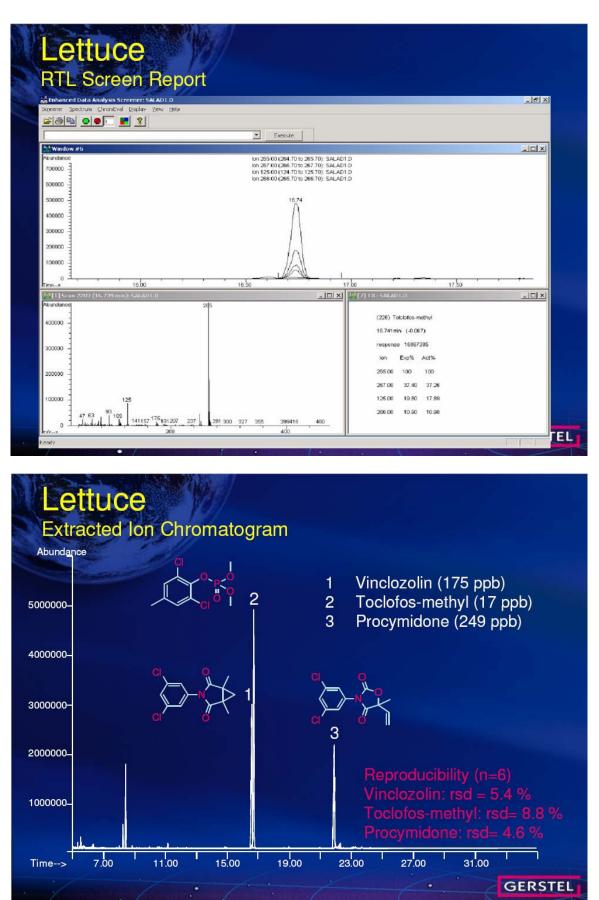

- MS becoming standard detector
- Moving from target compound analysis to multi-residue methods (MRM)
- Lower detection limits (< 10 ppb)
- Miniaturization of sample preparation
 - reduction of solvent consumption (500mL/sample)

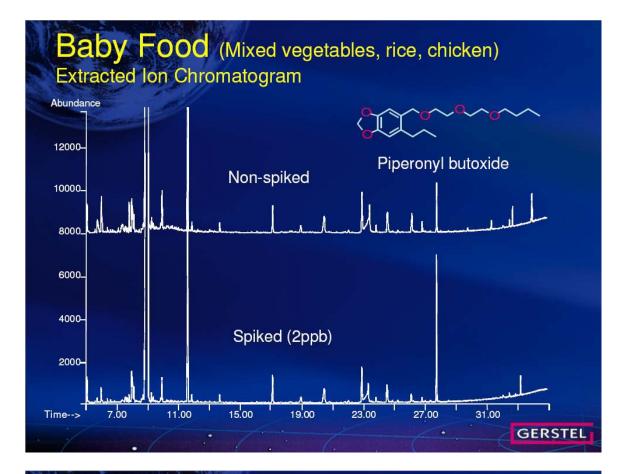

- automation (multi-step labor intensive)
- higher sample throughput

Summary of Twister Advantages

- Eliminates solvent
 extraction steps
- Eliminates most nonvolatile and polar matrix interference
- Allows parallel sample preparation minimizing instrument run time
- Stir bars are reusable

- Analytes are stable for days on stir bar allowing field sampling
- Extremely low detection limits possible (low ppt)

GERSTEL

- Excellent bar-to-bar reproducibility
- Analyte recovery is predictable

METHAMPHETAMINE AND BEYOND

Di Rienzo, Robert P.; DataChem Laboratories, Inc. Reynolds, John M.; DataChem Laboratories, Inc. Wade, Richard W.; DataChem Laboratories, Inc.

Newsweek magazine (August 8, 2005) calls methamphetamine America's most dangerous drug. "It creates a potent, long-lasting high - until the user crashes and too often, literally burns...." Newsweek calls attention to the dramatic surge in methamphetamine use which is no longer geographically isolated to the West but is used all across the United States. Methamphetamine use has also spread across the socioeconomic ladder and is no longer used primarily by the poor.

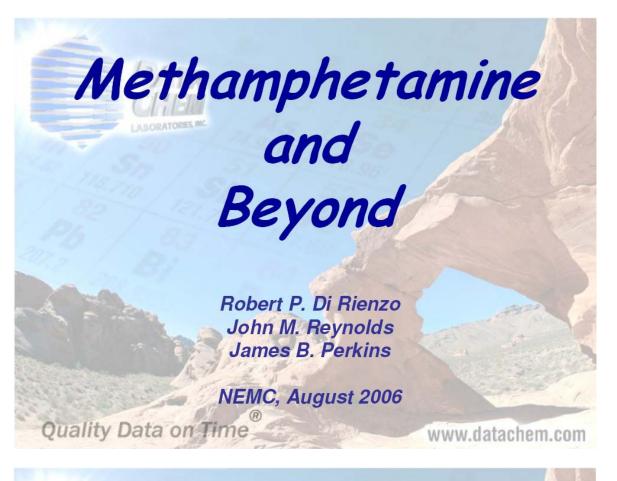

Health and hazardous safety concerns for illicit drug labs extend beyond methamphetamine.

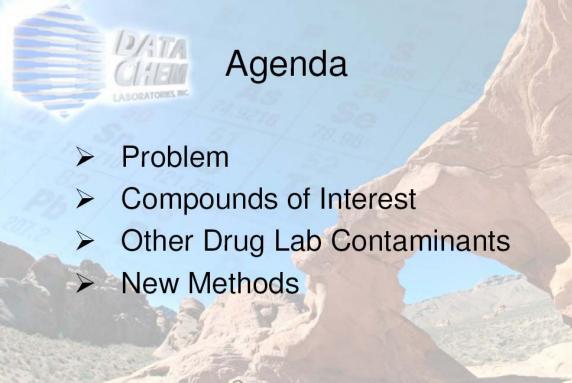

Contamination and exposure may be from a number of other drugs, precursors, contaminants or adulterants. Identification and analysis of these compounds may be important depending on the information needed for the sampling site.

It may be desirable to identify precursors used for the process of drug synthesis. As various drugs become harder to manufacture from certain precursors due to tighter restrictions, new synthetic procedures, new precursors, and new drugs appear in order to meet demand.

Adulterants are substances intentionally or unintentionally added to illicit drugs in the process of production or distribution. Adulterants may exist as "impurities" which are unintentional by-products from manufacture or from impure starting material. Such impurities may help identify the nature or source of the starting material or the process being used to create the illicit drug. The identification of starting material may be important in obtaining convictions and in shutting down such sources.

To protect human health and safety, to identify contamination and to monitor cleanup of clandestine drug labs, methods for analysis of methamphetamine and other illicit drugs have been developed for this rapidly growing concern.

Dump site contaminates creek Fish found dead in South Canal Creek near Highway 59

By MIKE DE LA CRUZ Staff Writer

A Caltrans worker found what could be a methamphetamine lab dump site, said sheriff's Deputy Wayne Hutton.

The worker was sweeping the shoulder of Highway 59 north of Oakdale Road Wednesday shortly before noon when he noticed empty industrial-size cans and dead fish in South Canal Creek, where it intersects the highway, and immediately reported the incident.

Soon a Merced County Sheriff's Department deputy, the California Highway Patrol, and officials from the state Department of Forestry, county Health Department, and state Department of Fish and Game, responded.

Sheriff Tom Sawyer, on scene, said any hazardous materials are treated very seriously because of the unknown levels of toxicity. "So we always have a full-blown response until we analyze the contents," he said.

Sheriff's Deputy Wayne Hutton, investigating the incident, said 12 empty 5-gallon alcohol cans, 57 empty 1-gallon alcohol cans, and 10 gray 5gallon cans without labels, were found. Alcohol is one of the ingredients in methamphetamine, also known as crank, the deputy said.

The cans were crushed and empty and had been transported to the creek in black trash bags. Hutton said. What was originally thought to be a major hazardous spill was downgraded when the cans were found to be empty and crushed.

It is now believed the cans could come from a minor dump site for chemical containers from an illegal methamphetamine laboratory, Hutton said. Hutton said numerous large dead fish were found floating in the slowmoving creek near the dumped cans.

"However, fish farther up the creek on either side were alive and swimming," Hutton said.

But the water will be tested to determine if it is safe for the cattle grazing on both sides of the highway.

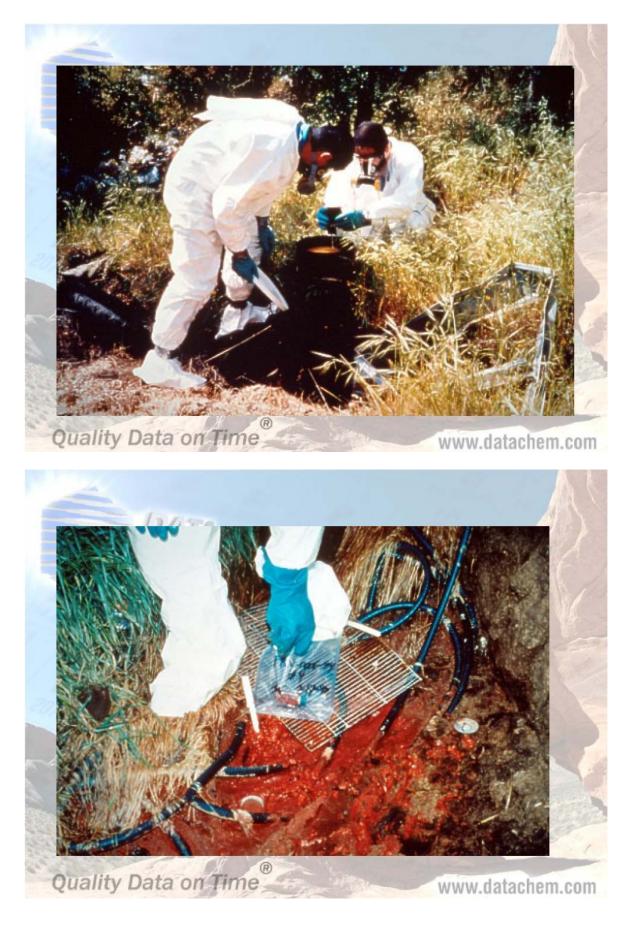

The land on the west side of the highway is owned and the land on the opposite side is leased by the Bert Crane Ranch.

Metamphetamine Laboratory Hazards

Chemical	Hazards
Pseudoephedrine	Ingestion of doses greater than 240 mg causes hypertension, arrhythmia, anxiety, dizziness, and vomiting. Ingestion of doses greater than 600 mg can lead to renal failure and seizures.
Acetone/ ethyl alcohol	Extremely flammable, posing a fire risk in and around the laboratory. Inhalation or ingestion of these solvents causes severe gastric irritation, narcosis, or coma.
Freon	Inhalation can cause sudden cardiac arrest or severe lung damage. It is corrosive if ingested.
Anhydrous ammonia	A colorless gas with a pungent, suffocating odor. Inhalation causes edema of the respiratory tract and asphyxia. Contact with vapors damages eyes and mucous membranes.
Red phosphorus	May explode as a result of contact or friction. Ignites if heated above 260° C. Vapor from ignited phosphorus severely irritates the nose, throat, lungs, and eyes.
A CAR	Source: DEA Office of Diversion Control

Methamphetamine Laboratory Hazards

Chemical	Hazards
Hypophosphorous acid	Extremely dangerous substitute for red phosphorus. If overheated, deadly phosphine gas is released. Poses a serious fire and explosion hazard.
Lithium metal	Extremely caustic to all body tissues. Reacts violently with water and poses a fire or explosion hazard.
Hydriodic acid	A corrosive acid with vapors that are irritating to the respiratory system, eyes, and skin. If ingested, causes severe internal irritation and damage that may cause death.
lodine crystals	Give off vapor that is irritating to respiratory system and eyes. Solid form irritates the eyes and may burn skin. If ingested, cause severe internal damage.
Phenylpropanolamine	Ingestion of doses greater than 75 mg causes hypertension, arrhythmia, anxiety, and dizziness. Quantities greater than 300 mg can lead to renal failure, seizures, stroke, and death.

Two Novel Reversed Phase HPLC Columns for the Baseline Resolution of Explosives Compound of Environmental Interest

Douglas Later, Xiaodong Liu, Andrea Heckenberg, Ilze Birznieks, and C. Pohl

The 22nd Annual National Environmental Monitoring Conference Arlington, Virginia August 28—31, 2006

Overview

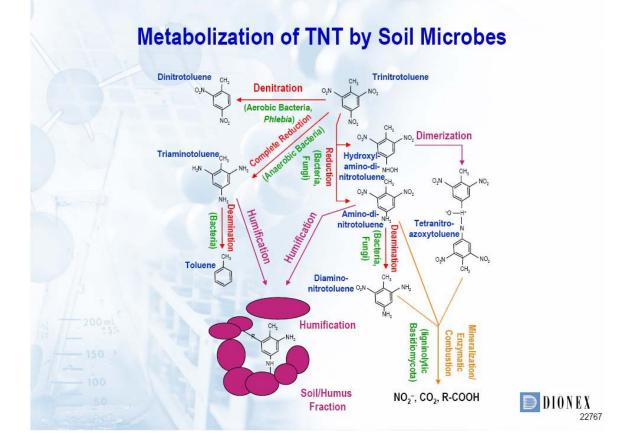

- Background
 - Explosives and the Environment
 - Explosives Analysis by HPLC (U.S. EPA Method 8330)
 - Current State of the Art
- Acclaim[®] Explosives E1 Column A Primary Column
- Acclaim Explosives E2 Column A Confirmatory Column
- Summary
- Acknowledgements

Explosives and the Environment

- Explosives toxic, mutagenic
- Polluted areas soil and groundwater
 - Military and civilian firing ranges
 - Munitions and explosives manufacturing plants
 - Commercial explosive-use sites, e.g. mines
- Major explosive contaminants in environment
 - HMX, RDX, Tetryl, and TNT
 - Manufacturing impurities of TNT (DNTs, NTs, TNB, DNB)
 - Degradation products of TNT (e.g., 2-A-4,6-DNT, 4-A-2,6-DNT, etc.)

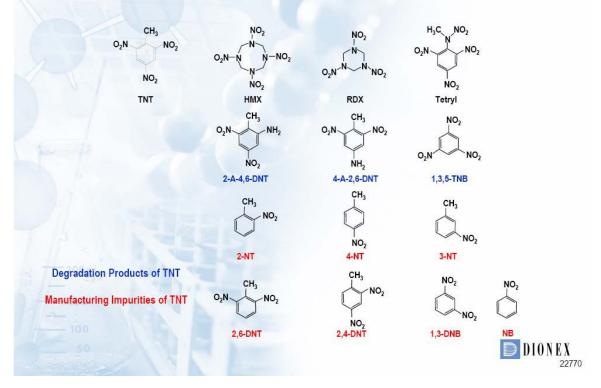

609

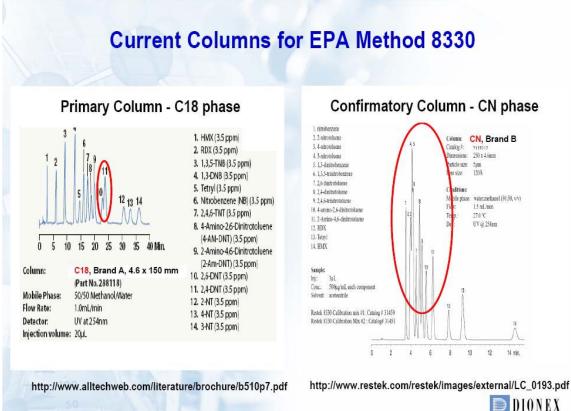

U.S. EPA Method 8330

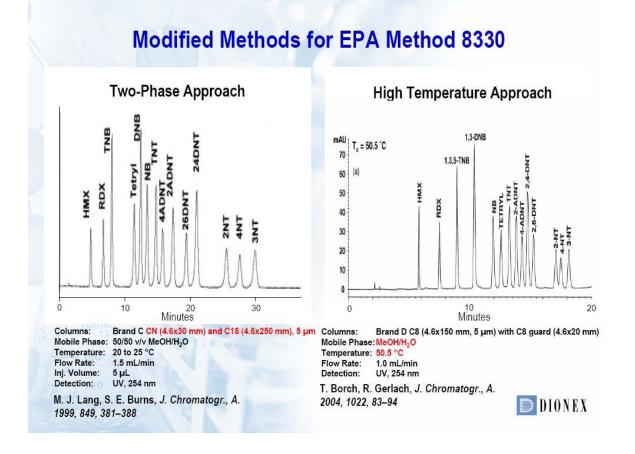

- "Method 8330 is intended for the trace analysis of explosives residues by HPLC using a UV detector. This method is used to determine the concentration of 14 target explosives compounds in a water, soil, sediment matrix."
- Primary Column: C18 reversed phase HPLC column, 25-cm x 4.6 mm, 5 µm..."
- Secondary Column: CN reversed phase HPLC column, 25-cm x 4.6 mm, 5 µm..."
- "...all positive measurements observed on the C18 column must be confirmed by injection onto the CN column..."

14 Explosives in U.S. EPA Method 8330

Challenge

 To separate 14 explosives compounds in EPA method 8330

- With superior resolution
- On a single column
- Using EPA method 8330
 - » Isocratic method
 - » Moderate temperature (25 to 35 °C)
 - » MeOH/H₂O mobile phase system
- On a standard HPLC instrument

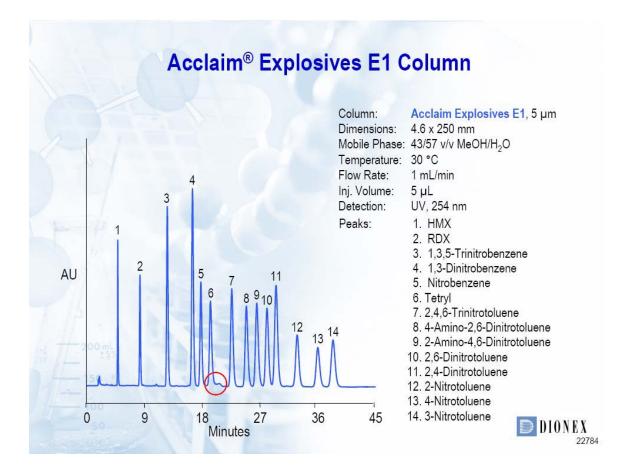

Solution – Acclaim[®] Explosives E1 & E2 Columns

A Total Solution by Dionex

Function Comparison

Acclaim[®] Explosives E1

- Superior separation power for all 14 compounds in EPA 8330
- Selectivity similar to the current primary columns (ODS)
- An excellent direct replacement for ODS columns

Acclaim Explosives E2

- Superior separation power for all 14 compounds in EPA 8330
- Selectivity complementary to the current primary columns
- Ideal selectivity for separating nitro aromatics, nitramines, and nitrate esters in a single run
 - An unparalleled alternative column

Conclusion

Acclaim[®] Explosives HPLC columns provide:

- Superior capability for separating all 14 explosives in EPA 8330, as well as other explosives of great importance (i.e. PETN, EGDN, etc)
- Complementary selectivities, providing a complete HPLC solution
- More accurate results and higher throughput

Use for regulatory compliance monitoring?

 Barry Lesnik, RCRA National Organic Methods Program Manager, U.S. EPA-OSW/EMRAD has confirmed the following:

"The Disclaimer language in SW-846 states that the instruments and accessories listed in the methods are those that were used to develop the methods. Other columns can be used provided that they can be demonstrated to perform appropriately for their intended applications."

Chemical Speciation – Hg, Se, and Br Species

SPECIATION OF MERCURY IN HUMAN HAIR

Fahrenholz, Timothy; Duquesne University Kingston, Skip H.M.; Duquesne University Pamuku, Matt; Applied Isotope Technologies, Inc. Rahman, Mizanur G.M.; Duquesne University

Mercury has been well known as an environmental pollutant for several decades. Generally, human uptake of mercury occurs in the following manners: by consuming methylmercury from fish as a major dietary contaminant; by breathing mercury vapors emitted from various sources as metallic mercury, dental amalgams, and ambient air; and through injection of thimerosal containing vaccines. Hair mercury levels have been found to be indicative of dietary, environmental and occupational exposures to the mercury species. In order to assess the extent of mercury exposure and risk to health, it is essential to determine the levels of inorganic mercury and mercury species such as methylmercury.

To date, the methods for determining mercury species in hair have involved separate extractions and determinations of the inorganic mercury and organomercury species. The methods reported in the literature vary, in that some digest the hair sample while others extract the mercury species from hair without digestion. These methods are susceptible to artifact formation or degradation of mercury species during extraction or digestion processes. As none of these methods can measure and correct for species transformations, such as bi-directional inter-conversions between inorganic mercury to methylmercury, the EPA Method 6800 has been applied as both a diagnostic tool and a determinative technique for species quantitation. During this study, it was found that some methods induced transformation of both mercury species (inorganic mercury and methylmercury) simultaneously. Some other methods induced only demethylation during extraction.

EPA Method 6800, applied as a diagnostic tool, was used in the evaluation of species transformations along with the simultaneous correction of both species shifts. It also provided a reliable and robust means to quantitatively evaluate the accuracy of many literature-reported protocols. Species inter-conversions that occurred after speciated isotopic spiking were quantitatively corrected by monitoring isotope ratios in each species. Method 6800 generated data and comparison of existing methods illustrate potential problem areas with respect to quantitation associated with sample preparation.

Evaluation of Literature Methods Used in Speciation of Mercury in Human Hair: Application of Speciated Isotope Dilution Mass Spectrometry (SIDMS, EPA Method 6800) as a Diagnostic Tool for Accurate Analysis

NEMC 2006

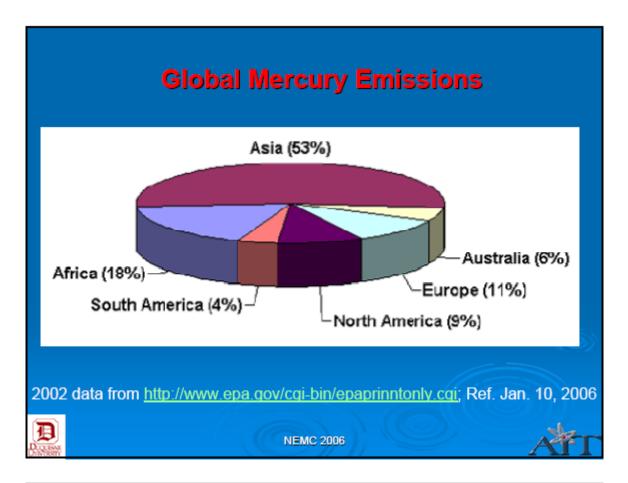

Outline

- Background information
- Evaluation of eight (8) literature methods for mercury speciation in human hair
- Introduction to the SIDMS equations and software
- Future directions

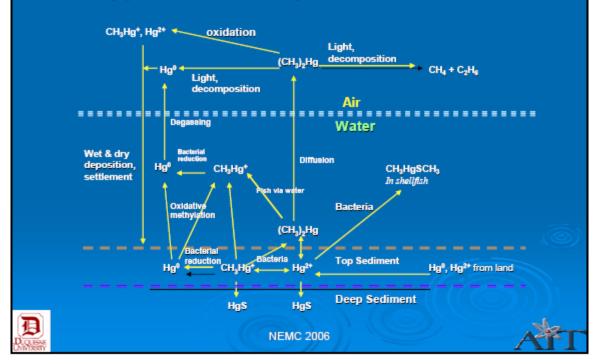

Mercury Species Conversion in Nature Type 1, 2, 3, ... species conversion

MERCURY EXPOSURE

Inorganic Mercury

- Hg^o widely used in domestic and industrial applications

Thermometers, thermostats, barometers Batteries, Fluorescent lights, Electrical switches Dental fillings and medical equipment Sold for use in folk medicine in some cultures Coal burning releases 99% of mercury of all species Hgº into the air (55% of US electric power is coal fire

Organic Mercury

 Methylmercury is formed in water and soil by bacteria; Exposure occurs through:

Eating contaminated fish or shellfish Larger and older fish usually have highest levels of mercury Phenylmercury used to control fungus in products before 1991 Exposure occurs through vapors in the air released : Exterior and oil based paints Caulks, Cosmetics and toiletries

NEMC 2006

Mercury Toxicity

Potent toxin

- Methylmercury deteriorates CNS; passes blood/brain barrier, impairs hearing, speech, vision and gait, causes involuntary muscle movements, corrodes skin and mucous membranes, causes chewing and swallowing to become difficult, and in severe cases irreversibly damages areas of brain.
- Hg⁰ passes blood brain membrane and convert into Hg²⁺.
- Hg²⁺ damages kidney
- Fetuses/children more susceptible

Disasters

- Japan 2000 poisonings 100 deaths (1956)
- Irag 6000 poisonings 400 deaths (1972)

Federal Mercury Limits

- The federal government set human limits of acceptable levels of mercury:
- 2 (ppb) parts of mercury per billion parts of drinking water (set by the EPA)
- 1 (ppm) part of methylmercury in a million parts of seafood (set by the FDA)

 0.1 milligram of organic mercury per cubic meter of workplace air and 0.05 milligrams per cubic meter of metallic mercury vapor for 8-hour shifts and 40-hour weeks (set by OSHA)

Methylmercury threshold levels in hair for neurotoxicity set by WHO is 50 ppm and by EPA is 10 ppm.

NEMC 2006

Assessment of Human Exposure to Mercury Species

Body fluid

- Blood methylmercury
- Serum methylmercury
- Urine inorganic mercury
- > Tissue
 - Nail inorganic mercury and methylmercury
 - Hair Inorganic mercury and methylmercury
 - Total mercury in hair for a normal person is in the range of 0.4 6 ppm
 - Hair to blood mercury ratio is 250:1
 - Hair mercury levels found to be a good indicator of dietary, environmental and occupational exposure
 - Concentration of mercury species in hair would be convenient as a biological marker

- Digestion
 - Acidic digestion
 - Basic digestion
- Extraction

LIQUID CHROMATOGRAPHIC MERCURY SPECIATION: A SUITE OF NEW TECHNIQUES EMPLOYING SOLID-PHASE EXTRACTIONS AND LIQUID-PHASE TRANSFERS AND SEPARATIONS

Shade Ph.D., Christopher W.; Quicksilver Scientific, LLC

In the 1990's, EPA Methods 1630 and 1631 set a new stage for mercury speciation analysis but it has always been a difficult and very expensive endeavor, and this expense arguably has hampered efforts at wide-scale environmental monitoring of methylmercury, the most toxicologically-relevant form of mercury. Though distillation/ethylation/GC/CVAFS (EPA Method 1630) is accurate; it requires extensive labor by a skilled technician and has not been automated, thus keeping the price for such analyses prohibitively high despite the passage of time. To surmount this inherent limitation, a new system for liquid phase transfers, trapping, and separations, centering on ligand-exchange reactions, has been developed.

Soft metals like Hg are almost never in their free-ion state, and thus the best way to manipulate them is to control their speciation with added ligands and then manipulate the formed complexes. Different ligands can be used that span a range of binding strengths and Brønsted basicities in order to effect a series of ligand exchange reactions to trap and/or separate inorganic and methylmercury. Hg/Thiourea - Ion Chromatography is an analytical system for methyl and inorganic mercury (MeHg and Hg^{II}, respectively) that uses an on-line thiol trap to concentrate MeHg and Hg^{II} from prepared sample solutions and then elutes them as charged Hg-Thiourea complexes for sequential separation, oxidation, and reduction to Hg⁰ for Cold Vapor Atomic Fluorescence Spectroscopy detection.

Thiourea's unique nature 1) creates cationic complexes with mercury giving a simple separation strategy, and 2) has very low Brønsted basicity, allowing sorption of mercury species from thiourea solutions onto a thiol resin at medium pH and elution from a thiol resin to the thiourea solution at low pH. The combination of thiourea, with its unique properties, as a ligand and the thiol trap, with its high binding strength, as a preconcentration method allows a greater flexibility in sample preparation chemistries than is permissible by the very condition-sensitive ethylation/purge-and-trap concentration of EPA Method 1630. This flexibility allows the analyst to use thiourea to back-extract solvent extractions (methylene chloride or toluene) or even to replace those solvents with solid-phase extraction media, and has the additional benefit of making the system ideal for simple monitoring of petrochemical products, such as oil or methane gas condensate.

Most importantly, the system features scalable sample preparation methods and automatable sample analysis, creating the potential for steeply reduced pricing of analyses and thus allowing greatly increased monitoring of this important neurotoxin.

What's an analyst to do?

Strong Acid...

and Polymer Resins...

Background

•Horvat, Liang, and Bloom (1992)

•incomplete recovery from HCI; better with Cu²⁺

•Depression of recovery correlated with LOI

•worst recovery and no effect of Cu on highest LOI

•We (Hudson Lab – UIUC) get weak results with $H_2SO_4/KBr/CuSO_4$ industrially-polluted wetland seds (60-80% recoveries)

•C.M. Tseng et al. microwave HNO₃

•Liang et al. (2003) find $HNO_3/CuSO_4 \sim distillation > H_2SO_4/KBr/CuSO_4$ (highly variable recovery)

•Hammerschmidt and Fitzgerald successfully use 2M HNO_{3} leaching on LIS

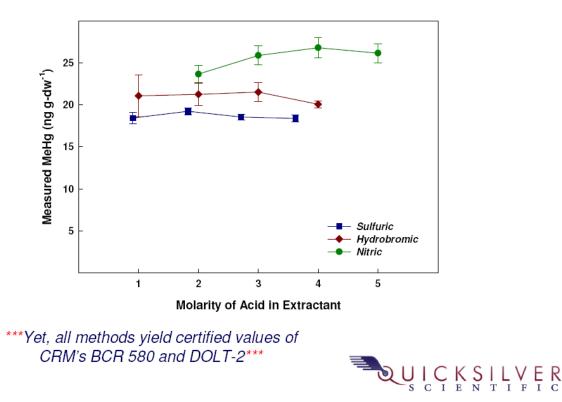

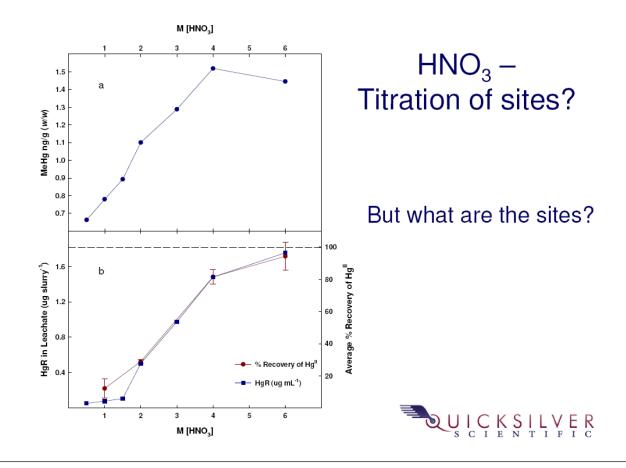

Acid Leaching/Solvent Extraction -low artifact/generally good recovery

- Leach in mineral acid and CuSO₄
- Toluene Extract (takes neutral MeHg complex and restricts the bulk of anionic Hg^{II})
- Thiourea back-extract
- · Load back-extract on thiol trap

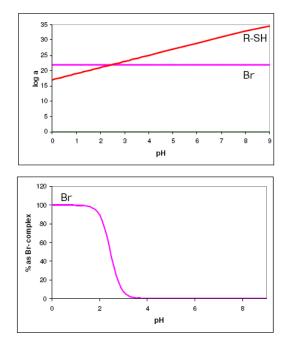

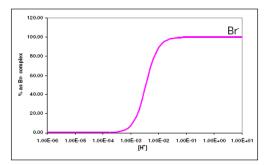

Effects of Acid Types

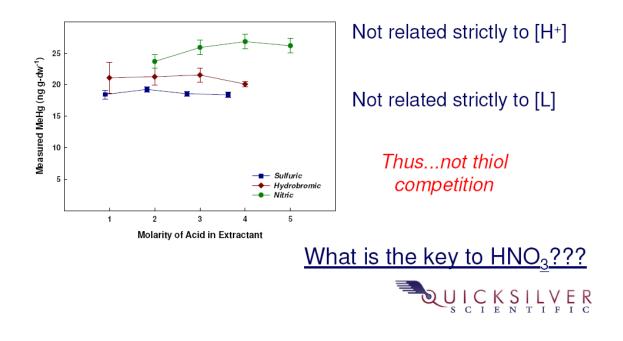

Thiol – Bromide Competition

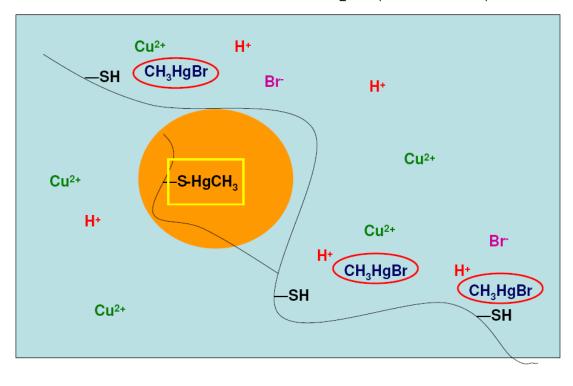

Effects of Acid Types

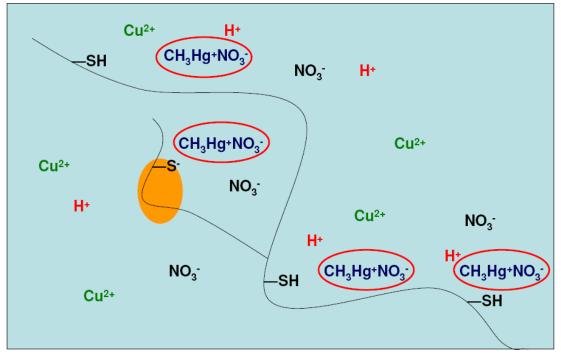

The Hydrophobic Pocket Theory

- Humic material condenses and becomes hydrophobic upon acidification
 - protonation of carboxyl and phenolic groups
- Any hydrophobic compounds in matrix will gather around hydrophic humics
 - natural from flora lipids, waxes
 - anthropogenic petrochemical residues
- Results in humic thiol functionalities being hidden from aqueous acidic extractant
 - both leaving some MeHg behind and giving solbilized MeHgBr a place to partition into and get stuck

Thiol-containing Hydrophobic Pockets - limiting access of aqueous acidic extractant (H₂SO₄/KBr/CuSO₄)

Thiol-containing Hydrophobic Pockets – Attacked by HNO_3 ($HNO_3/CuSO_4$)

Take Home Message...

-Highly-Processed Created Samples (e.g. CRM's) do not always reflect the difficult matrix of the real world.

-We need chemistries that can tackle the worstcase scenarios

PDVB – Polydivinylbenzene "Goodbye to solvents"

•Use SPE cartridges and vacuum extraction manifolds

•scalable, high-throughput

•Jordi Associates PDVB – 200mg

•Load with acid leachate (H₂SO₄/KBr, HCl, HNO₃)

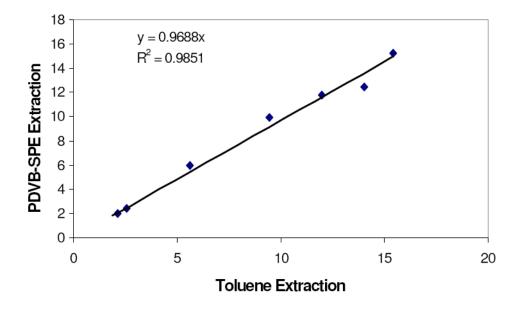

•Sorbs neutral MeHg-Cl,Br complexes and oxoanionic ion-pairs

•Elute with acidic thiourea as cationic MeHg-Tu complex

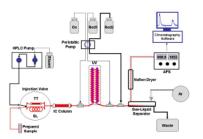

•Concentrate on thiol trap

Toluene-PDVB Comparison

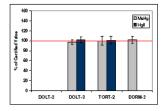

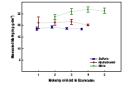

Conclusions

•Hg-Tu IC/CVAFS provides a robust and sensitive, automatable speciation and detection system for MeHg and Hg^{II}

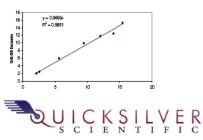

•Eluant leaching provides simple extraction for simulatneous MeHg and Hg^{II} analysis

•HNO₃/CuSO₄ provides superior release of MeHg from sediment sites over $H_2SO_4/KBr/CuSO_4$ by accessing sites unavailable to other acid leachants

•PDVB SPE provides scalable solvent-free alternative to MeCI and Toluene

ANALYTICAL METHODS FOR SELENIUM SPECIATION: THE GOOD, THE BAD, AND THE UGLY

Gerads, Russell and Gürleyük, Hakan; Applied Speciation and Consulting, LLC

The dissemination of information regarding the toxicity associated with different selenium species has significantly increased the demand for selenium speciation analysis. Historically, scientists and industrial experts have relied heavily on older methodologies (hydride generation) which retained considerable interferences and limitations. The facts associated with two different analytical methods for selenium speciation will be presented as they currently apply to real world samples.

ANALYTICAL AND PREPARATORY ISSUES ASSOCIATED WITH TOTAL SELENIUM AND SELENIUM SPECIATION ANALYSIS

Gerads, Russell and Gürleyük, Hakan; Applied Speciation and Consulting, LLC

Many treatment plants are struggling to meet the stringent NPDES permit limits on selenium discharges from their waste streams. While treatment of selenium remains to be a challenging task, different analytical methods can generate inaccurate results for total selenium and selenium speciation analyses compounding the complexity of the problem. Since important treatment decisions are made using these analytical results, the ramifications of generating poor analytical data cannot be understated.

Current EPA methods for the determination of total and dissolved selenium were not designed for the complex waste streams generated by treatment plants. The sample collection container, preservative, digestion technique, selenium species present in solution, and applied analytical method can have significant impacts on the representativeness of the results. In addition, significant biases have been identified with various analytical techniques for selenium speciation which are being applied throughout the industry and consistently fail to provide the necessary information to solve the problem.

Issues associated with various sampling, preservation, digestion, and analytical techniques will be discussed to identify their applicability to many environmental samples. A comparison between different analytical techniques for selenium speciation analysis will be presented and additional information regarding the interaction of certain selenium species will be reviewed to provide a more robust understanding of the complexity of selenium in the environment.

Improved Bromate/Bromide Speciation in Drinking Water by HPLC/ICP-MS

Pamela A. Perrone Ph.D., Wilhad M. Reuter Ph.D., Kenneth R. Neubauer Ph.D, Zoe A. Grosser Ph.D.

PerkinElmer Life and Analytical Sciences

ABSTRACT

Water for public consumption must be purified prior to distribution. A number of processes are used for water purification, including treatment with ozone to kill bacteria. While this method is effective, ozonolysis can also convert bromide (a natural component of many waters) into bromate (BrO₃⁻), a carcinogen. Therefore, the need exists to measure bromate in drinking waters, which means that it must be measured separately from other forms of bromine. Current methods for measuring bromate and bromide involve separating the bromine-containing components by ion chromatography and using ICP-MS as a detector monitoring bromine at m/z 79; this is the protocol stated in EPA method 321.8.

This work focuses on bromide/bromate speciation by ion chromatography using Dynamic Reaction Cell (DRC) ICP-MS as the detector. Methodology on a new column is developed, speeding up the method by more than a factor of two. Waters from around the world are analyzed, some showing a variety of peaks. Techniques to identify the peaks are explored and a scheme for analysis is presented.

INTRODUCTION

Bromine is a natural component found in waters, most commonly as the bromide ion – Br. A common procedure for purifying drinking waters is treatment with ozone to kill bacteria. A byproduct of ozonolysis is the conversion of bromide to bromate (BrO_3), a known carcinogen. Therefore, a need exists to measure both bromide and bromate in drinking waters, as opposed to total bromine content.

Our earlier work on bromine speciation focused on separating Br⁻ and BrO₃⁻ via anion exchange HPLC, and detecting the species with ICP-MS¹. The method proved rugged, but required eight minutes per sample. This work focuses on significantly decreasing the analysis time and also explores the possibility of separating other bromine-containing compounds which were found in several water samples.

EXPERIMENTAL

HPLC Conditions

A PerkinElmer Series 200 HPLC system, consisting of a quaternary pump, autosampler (with polypropylene vials), vacuum degasser, and peltier column oven, was used for all analyses. The separation was done with an anion exchange column (ZirChrom[®]-SAX ; ZirChrom Separations Anoka, MN USA).

Both isocratic and gradient HPLC methods were explored. For samples containing only bromide and bromate, the isocratic method was preferred due to the higher sample throughput. For samples containing additional bromine compounds, the gradient method was used. Details of both methods are shown in Tables 1 and 2, respectively. It should be noted that no pH adjustments were made on the mobile phases; the pHs used were those that resulted from mixing the mobile phase components at the concentrations specified.

	4 min at 100% B		

Table 2: HPLC Gradient Method Parameters

ICP-MS Conditions

Detection of the HPLC eluent was accomplished with an ELAN DRC II (PerkinElmer/Sciex, Shelton CT, USA). Instrumental conditions are listed in Table 3. All analyses were done in standard mode (i.e., no reaction gas was used) monitoring Br⁺ at m/z 79. Those samples which produced chromatograms containing additional peaks were also analyzed in DRC mode, monitoring BrO⁺ at m/z 95 and 97. The presence of the same peaks at both bromine isotopes in DRC mode (as well as in standard mode) confirms that the additional peaks contain bromine and are not the result of interferences.

RPq	Standard Mode - 0.25 DRC Mode - 0.50	

Table 3: ICP-MS Conditions

Standards and Samples

Bromide and bromate standards were made daily from 1000 mg/L stock solutions (Spex, Charleston, SC, USA) by dilution in ASTM Type I water.

Samples consisted of bottled waters purchased at local grocery stores from various countries and water collected directly from the tap. No sample preparation or dilutions were used, aside from filtering the waters which contained visible particulates.

Software

All instrument control and data processing and analysis was accomplished with Chromera[™] software (PerkinElmer LAS, Shelton, CT USA). Peak areas and external calibration curves were used for quantitative measurements. The calibration standards were diluted with ASTM Type I water, and the concentration levels were chosen to cover the range where the majority of species were found, although occasional samples produced concentrations higher than the highest calibration standard.

RESULTS AND DISCUSSION

Figure 1 shows a chromatogram of a 10 μ g/L mixed standard containing both bromate and bromide. The species are separated and baseline-resolved in less than three minutes. Figure 2 displays a chromatogram of a 1 μ g/L mixed standard. The intensities of the peaks are about two times baseline noise, signifying the lower level which can be measured. Larger injection volumes would allow lower levels to be measured, but could overload the column at higher concentrations.

Figure 1: Chromatogram (Isocratic LC Method) of a Standard Containing 10 μ g/L of Bromide and Bromate

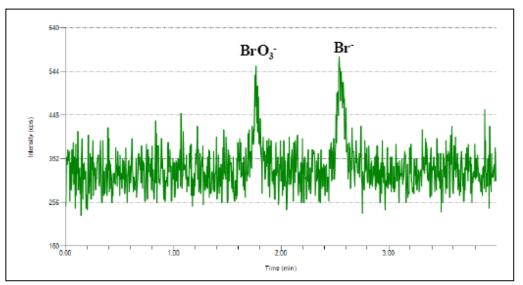

Figure 2: Chromatogram (Isocratic LC Method) of a Standard Containing 1 μ g/L of Bromide and Bromate

Once the separation was established, the method was applied to a number of drinking water samples. To determine the reliability of the method, the samples were measured in duplicate on four non-consecutive days; the results appear in Table 4. The small variation in the results indicates the robustness of the method. Additionally, a single sample was analyzed 49 times consecutively over a period of 3.75 hours. Figure 3 shows the chromatograms overlaid from this study, as well as the average concentration and standard deviation of the measurements. Additionally, the relative standard deviation of the retention times for both peaks is 0.5 and 0.4, respectively. Taken together, these tests demonstrate the ruggedness and repeatability of the method.

Table 4: Quantitative Determination of Bromide and Bromate in Water Samples Over Four Days (All units in µg/L)

All samples are bottled waters, except China 3 and China 5 which are tap waters

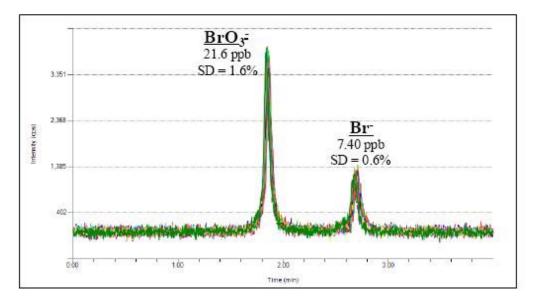

Figure 3: Overlay of 24 Chromatograms (Isocratic LC Method) of a Water Sample Obtained by Consecutive Injections - The average concentrations and standard deviation for each species are shown.

Figure 4 displays chromatograms of two samples which contain peaks in addition to bromate and bromide. To confirm that these peaks are really Br-containing species and not interferences, these samples were analyzed in DRC mode. For this study, BrO⁺ was monitored at m/z 95 and 97, representing both bromine isotopes. The conversion of Br⁺ to BrO⁺ was accomplished by reaction with N₂O in the reaction cell, according to the following gas phase chemical reaction²:

 $Br^+ + N_2O \rightarrow BrO^+ + N_2$ $k = 2.80 \times 10^{-10} \text{ cm}^3 \text{s}^{-1}$

The relatively high value of the rate constant k signifies that the reaction occurs rapidly, indicating that it is easily accomplished in the reaction cell.

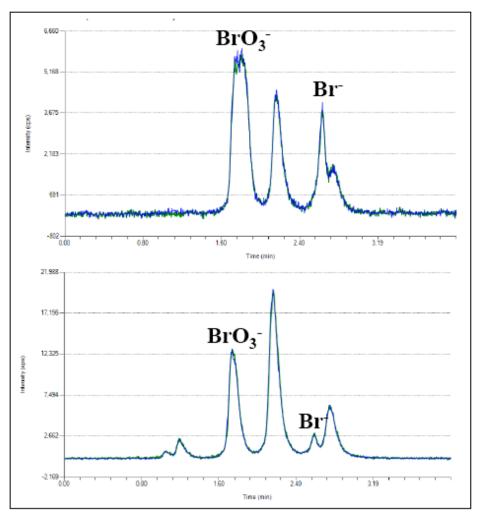

Figure 4: Chromatograms (Isocratic LC Method) of a Water Sample Containing Multiple Peaks: Bromide, Bromate, and Unidentified Species

Figure 5 shows overlaid chromatograms of BrO⁺ at m/z 95 and 97 for the two samples displayed in Figure 4. Because the chromatograms of both bromine isotopes in DRC mode are the same and match the chromatograms acquired in standard mode (Br 79), it can be concluded that the extra peaks are Br-containing species and not interferences.

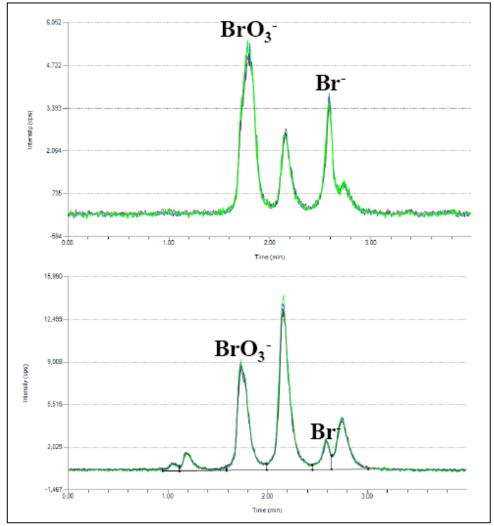

Figure 5: Chromatograms (Isocratic LC Method) of the Same Samples as in Figure 4, but Acquired in DRC Mode - For each sample, 2 chromatograms are overlaid: BrO⁺ at m/z 95 and 97

A gradient HPLC separation scheme was then developed to separate the additional compounds. Figure 6 shows chromatograms of the two water samples shown in Figure 4, but with a gradient HPLC method. The additional peaks in Figure 6 (as compared to Figure 4) confirm the presence of additional Br-containing species and indicate the need to perform a gradient separation to obtain true BrO₃⁻ concentrations. Further confirmation is presented in Figure 7, which shows the DRC-mode chromatograms for the gradient separation of the samples in Figure 6. Table 5 shows the quantitative results of bromate and bromide for the water samples analyzed under the gradient method.

When comparing the results of the isocratic and gradient separations in Tables 4 and 5, a few waters showed higher bromate concentrations with the isocratic method than the gradient method (Thailand 1 and 3, China 3 and 4). The reason for this is incomplete separation of unidentified species which co-elute with bromate with the isocratic method.

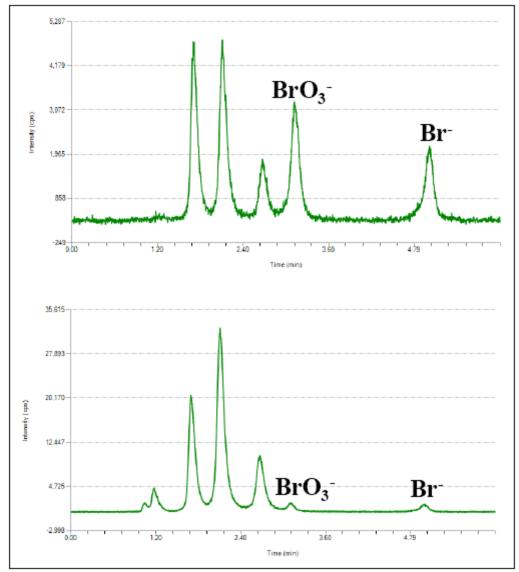

Figure 6: Chromatograms of the Samples in Figure 4, but Obtained with a Gradient LC Method

Although this incomplete separation leads to false high results, the combination of the isocratic and gradient methods could be used in tandem, with the isocratic method used for rapid screening, and the gradient method used for samples showing bromate concentrations above a pre-defined level method with the isocratic method. Since both methods use the same column and mobile phase components, switching between methods is simple.

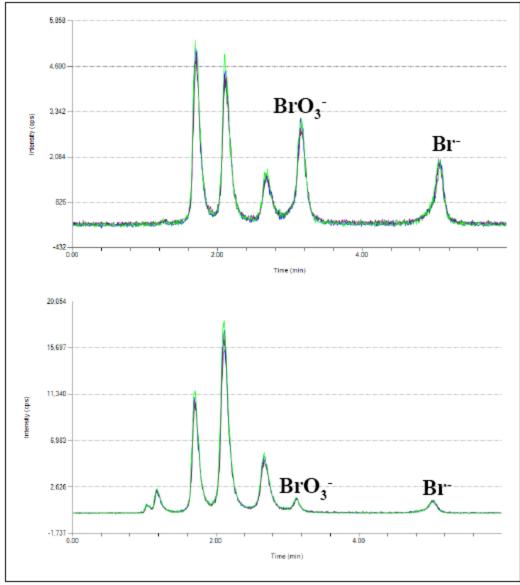

Figure 7: DRC-mode Chromatograms of the Samples in Figure 6, Obtained with a Gradient LC Method

It should be noted that no work was done to identify the additional bromine species. This could be accomplished with HPLC/ICP-MS by analyzing other known bromine-containing compounds and matching retention times with the unidentified bromine compounds. Another option would be to use LC/MS, which might allow the unknown species to be identified by examining the fragmentation pattern of the compounds. However, a main limitation of LC/MS is it's low-sensitivity, relative to LC/ICP-MS.

CONCLUSION

This work has demonstrated a rapid, robust method for separating and measuring bromide and bromate in drinking waters. The separations are accomplished in less than three minutes and proved to be repeatable from injection to injection and over several days. For those waters containing additional bromine-containing species, a gradient HPLC method was established. Taken together, the isocratic separation scheme can serve as a rapid screening method; those samples which contain additional bromine species can then be analyzed by the longer gradient method. If lower levels need to be measured, the injection volume of the HPLC autosampler can be increased.

Bromate

- Bromide (Br-) is naturally occurring in water, bromate (BrO₃-) is not
- Bromate forms when water containing bromide is treated with ozone purification
- Bromate is toxic with suspected carcinogenic properties
- > Regulated US drinking water MCL is 10 μ g/L (FR Dec 16, 1998)
- > FDA mandated 10 μ g/L limit in bottled water (2002)
- Added to California proposition 65 list

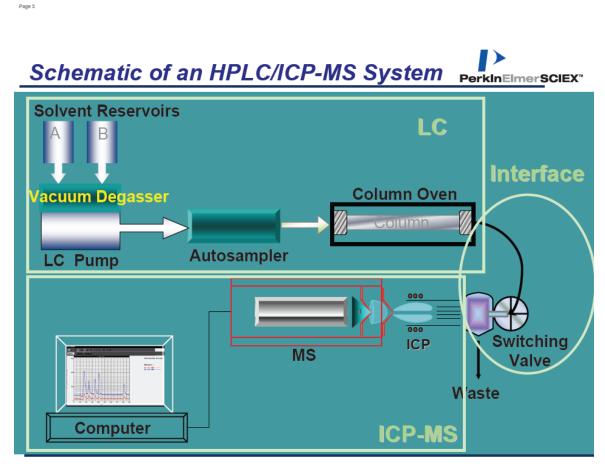

Page 2

US EPA Method 321.8

- > Developed in 1997 for bromate analysis
- > lon chromatography used for separation
- > Five bromine-containing species separated in 12 minutes
- > MDL of 0.3 µg/L determined for bromate
- > 1997 is a long time ago in speciation development
- Newer information on occurrence and typical levels may aid in refining the method
- The possibility of multielement work may more effectively use the detector

Page 5

Challenges

- > Which species are important?
- Developing a chromatographic method to separate the various species of interest
- Understanding the effects of different matrices on the chromatography

Page 6

Previous Work - Ion Exchange Chromatography

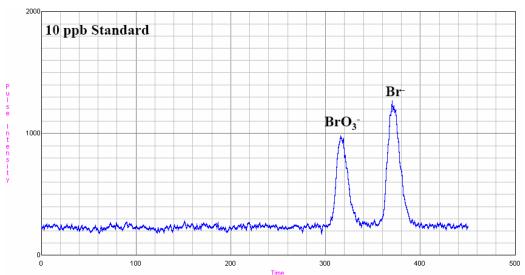

PerkinElmer**SCIEX**[™]

- Method developed to separate two species most often found in drinking water, Br⁻ and BrO₃⁻
- Use Hamilton PRP-x100, 5 µm x 15 cm column (anion exchange)
 - Same column as for As speciation in urine
 - Different mobile phase
- > Advantages
 - Achieves good separation
 - Simple mobile phase (HNO₃ + NH₄OH)
 - Clean mobile phase components
- Disadvantages
 - Longer chromatography than desired

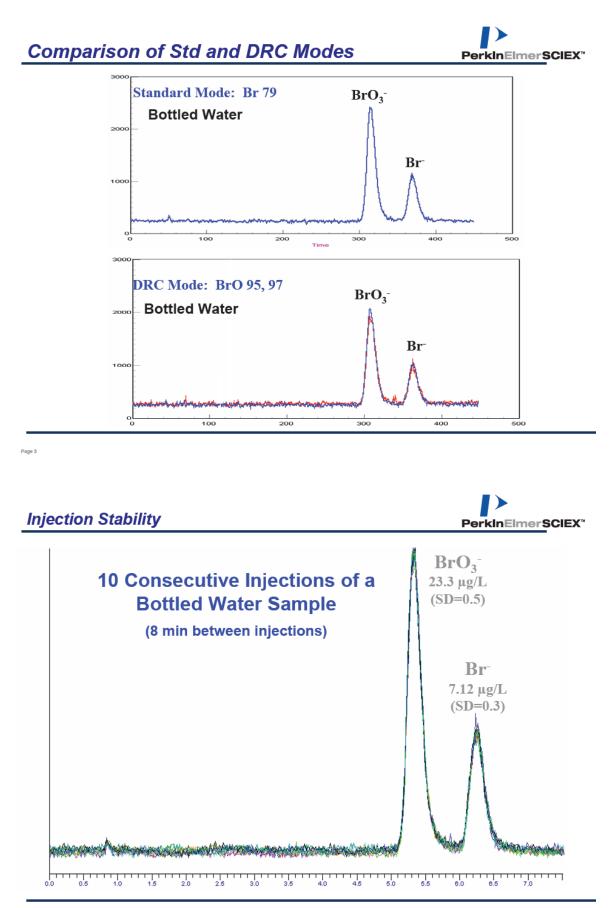

Page 7

Ion Exchange Chromatography

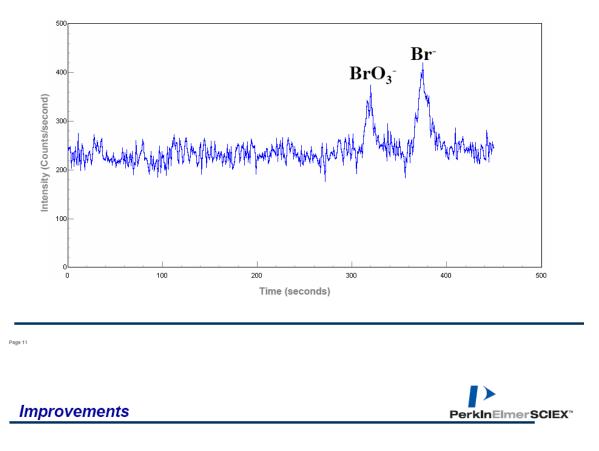

Good separation of the components of interest!

Bromine Speciation by HPLC/ICP-MS, Application Note 007303_01, PerkinElmer Life and Analytical Sciences, Shelton, CT USA

Low Concentrations

Chromatogram of a standard containing 1 μ g/L each of bromate and bromide.

- The original method takes 8 minutes for the chromatography to occur
- Faster chromatography would provide a better match to the detector (ICP-MS) and provide better throughput

Inorganic Methods

IMPLEMENTATION OF THE METHODS INNOVATION RULE AS A MAJOR FACTOR IN THE RCRA PERFORMANCE-BASED MEASUREMENT (PBMS) PROGRAM

Lesnik, Barry; U.S. EPA Office of Solid Waste-EMRAD

This talk will give a brief overview of the performance-based measurement approach to project planning and analytical methods selection and how it applies to the RCRA Program. It will also cover the basic changes to the RCRA regulations as a result of the promulgation of the Methods Innovation Rule (MIR) on June 14, 2005 and its effect on the regulatory and regulated communities, particularly enforcement and compliance. It will also cover the changes in how analytical methods will be added to SW-846.

IMPLEMENTATION OF THE METHODS INNOVATION RULE (MIR) AS A MAJOR FACTOR IN THE RCRA PERFORMANCE BASED MEASUREMENT (PBMS) PROGRAM

Barry Lesnik U.S. Environmental Protection Agency Office of Solid Waste – Methods Team

Major Topics to Be Covered

- 8 What is the Methods Innovation Rule (MIR)?
- 8 What will the MIR do and not do?
- 8 How will it affect the existing RCRA Program?
- 8 What are the responsibilities of Regulators and the Regulated Community under the Performance Approach?
- 8 What are "appropriate methods"?

Some IUPAC Definitions (Ref. 1)

- 8 Rational Method a method that determines one or more identifiable chemicals or analytes for which there may be several equivalent methods of analysis available
- Empirical Method a method that determines a value that can be arrived at only in terms of the method per se and serves, by definition, as the only method for establishing the measurand. (used to measure "method-defined parameters" or MDPs)

What is the MIR?

- The Methods Innovation Rule, or MIR, was designed to remove the unnecessary requirements to use only SW-846 methods for RCRA applications that did not require the use of empirical methods.
- The MIR allows more flexibility in RCRA-related sampling and analysis using rational methods, which is one of the Agency's steps towards implementing the Performance Approach (formerly PBMS).
- The MIR was published in the *Federal Register* as a Proposed Rule on October 30, 2002 (67 *FR* 66251).
- The MIR was published in the Federal Register as a Final Rule on June 14, 2005 (70 FR 34537).

What Will the Final MIR Do?

- Removes unnecessary required uses of SW-846 methods in the RCRA regulations and returns SW-846 to its originally intended purpose, as a guidance document
- Finalizes SW-846 Update IIIB
- Allows the Agency to fully implement the Performance Approach in the Federal RCRA Program
- Allows the Agency to publish rational SW-846 methods as guidance rather than through the formal Rulemaking process

Why is EPA Removing Unnecessary Required Uses of SW-846?

- EPA wants to allow more flexibility in RCRA-related sampling and analysis, and concentrate on measurement objectives rather than measurement technologies, i.e., the Performance Approach.
- Some regulated entities told EPA that they would like to use other reliable methods during RCRA compliance.
- Therefore, EPA has finalized the MIR to remove unnecessary requirements to use SW-846 methods in the RCRA regulations, and allow the use of other appropriate methods.

What Required Uses of SW-846 Methods Are Necessary and Have Not Been Removed?

- The MIR did not remove requirements to use a method if it is the only method capable of measuring the regulated property – i.e., empirical methods used to measure method-defined parameters (MDPs). Regulated entities will still have to use those methods.
 - For example, 261.24 (a) requires the use of SW-846 Method 1311, TCLP, for toxicity characteristic analysis
 - The required use of the TCLP is necessary and thus has not been removed by the MIR
- We identified 29 SW-846 methods that may be required to analyze RCRA-required MDPs.

What Required Uses of SW-846 Methods Are Not Necessary and Have <u>Been</u> Removed?

- Other required uses of SW-846 methods do not involve the analysis of required MDPs.
 - For example, § 260.22(d)(1)(i), part of the delisting regulations, requires the use of SW-846 methods to delist a waste listed with code "T".
- For these regulations other methods can be used without affecting the regulatory decision, provided the project data quality objectives (DQOs) are met.
- The required use of only SW-846 methods is not necessary, and the use of other appropriate methods is allowed.

What Might be the Impact of Removing Required Uses of SW-846?

- Regulated entities will be able to use other methods besides the SW-846 methods, when appropriate. They might choose these other methods to save costs and time.
- This greater flexibility will also stimulate the development and timely use of innovative and more cost-effective monitoring technologies and approaches in the RCRA Program.

Now That We Have Adopted the Performance Approach, What Are the Responsibilities of the Affected Entities?

- Regulatory Agency Responsibilities
 Regulators and Permit Writers
 Enforcement
- 8 Regulated Community

Regulator Responsibilities Under the Performance Approach

- Regulators must establish clearly delineated DQOs appropriate for regulatory activities. Examples include:
 - Permits will need to include regulatory limits for target analytes with tolerable error rather than a general reference to use a particular method
 - Specific DQOs including tolerable error for demonstration of compliance to regulatory criteria need to be written directly into regulations.

Regulator Responsibilities Under the Performance Approach

- Enforcement approach would be to determine if the quality of the data generated and documentation provided met DQO/MQO requirements, rather than whether a particular method was followed exactly
- 8 EPA-published methodology is guidance

Responsibilities of Regulated Community Under the Performance Approach

- Generator is responsible for demonstrating regulatory compliance
 - Selection of appropriate methods to demonstrate ability to meet project-specific DQOs/MQOs
 - Must maintain appropriate documentation for this demonstration, e.g., SAP, SOPs, QC data, etc.

Responsibilities of Regulated Community Under the Performance Approach (Contd.)

Allowable Flexibility

- Any method that yields acceptable data quality for a particular application may be used (See "Appropriate Method" slides)
- B Published methods may be modified, as necessary, to generate acceptable data quality without pre-approval by EPA

Responsibilities of Regulated Community Under the Performance Approach (Contd.)

Allowable Flexibility (Contd.)

- New technology may be used as soon as it is developed and validated, provided that it can be demonstrated to be appropriate for generating acceptable data quality for a particular application
- The facility is responsible for meeting DQOs/MQOs and documenting that they were met for a particular application

How Will the Performance Approach Change the Current Way of Doing Business?

- The data review focus would shift from whether a method was exactly followed to whether the methods used were appropriate to meet the required DQOs/MQOs.
- It will require the generator to provide more substantial documentation than is currently being generated in most programs whether EPA-published methods are used or not.

What Is An "Appropriate Method"?

The MIR replaces unnecessary required uses of SW-846 by allowing the use of other "appropriate methods such as those found in SW-846 or other reliable sources."

- 1. Appropriate methods are reliable and accepted as such in the scientific community.
- 2. Appropriate methods generate effective data -data of sufficiently known and of adequate quality for supporting the project-specific decisions.

What Is An "Appropriate Method"? (Contd.)

Simply stated, an "appropriate method" is one that can be demonstrated to be able to see the analytes of concern at the level of concern in the matrix of concern and generate data of appropriate quality to be used for its intended application, i.e., effective data.

Who Chooses the Appropriate Method?

- Choosing an appropriate method begins during project planning and involves all key participants.
- The regulated entity is ultimately responsible for compliance with the subject regulation.
- We recommend consultation with the regulating authority during method selection, if necessary, and with the laboratory that is ultimately doing the work.

What Are the Key Steps in Choosing an Appropriate Method?

- Identify regulatory requirements (e.g., the analyte, matrix, and regulatory action level), the decision to be made, and the data quality needed to support that decision.
- Identify analytical goals (including for example performance requirements related to the matrix and analyte detection, e.g., recovery and precision).
- Select a method believed to be capable of meeting the performance requirements and other goals.

What Are the Key Steps in Choosing an Appropriate Method? (Cont.)

- Seek guidance as needed during method selection, e.g., from your laboratory, your regulating authority and SW-846 Chapter Two.
- Identify the data quality objectives, the method to be used, and the quality control indicators and make sure to put them into the planning document (e.g., QAPP, WAP, SAP).

What Are the Key Steps in Choosing an Appropriate Method? (Cont.)

- Use the data generated during the implementation phase to demonstrate that the method is appropriate – to show that the criteria were met.
- The performance data in SW-846 methods are just examples and not requirements – the actual performance acceptance criteria should be project-specific.
- As part of a dynamic approach, method selection and optimization may be revisited during the implementation phase.

Why We Selected the "Appropriate Method" Approach

- 1. The appropriate method approach is universally applicable to the affected regulations and requires minimal regulatory revisions.
- 2. The appropriate method approach is not new to RCRA regulations.
- 3. Also, regulated entities already should be using a similar approach to determine if a method is appropriate to a particular waste and analytical purpose.

Does the MIR Add New Requirements to the RCRA Regulations?

No new requirements are added!

- The use of <u>other</u> appropriate methods will be an option, not a requirement.
- Regulated entities can still use the SW-846 methods, if they are appropriate for the intended application.
- EPA is not adding new testing or information collection and reporting requirements beyond what should already be done now.

Adoption by Authorized State Programs

- Authorized States do not have to adopt the removal of unnecessary required uses of SW-846 methods, although we strongly encourage them to do so.
- Adoption may not cause significant impacts because States should already review method selection and quality control data to determine regulatory compliance; and most entities will probably continue to use SW-846.

EPA to Offer Training and Guidance

- EPA plans to offer training to the States and other entities on the MIR concepts and practices via training modules, workshops, and fact sheets.
- We hope that training will help ensure consistent implementation of the MIR and limit any costs.
- Please provide us with feedback as to what major topics we need to cover and which audiences we need to address

The MIR Also Finalizes SW-846 Updates IIIB

- Update IIIB includes a revised Chapter Seven, removing the reactivity test guidance.
- Update IIIB includes empirical methods used in the analysis of MDPs, and most were revised to remove the unnecessary required use of SW-846 Chapter Nine.

Status of the RCRA Waste Sampling Draft Technical Guidance

- The RCRA Waste Sampling Draft Technical Guidance was noticed as part of the proposed MIR.
- We have currently addressed all comments and are working with OGC to determine whether there is sufficient change in content to warrant our putting it out again for public comment.

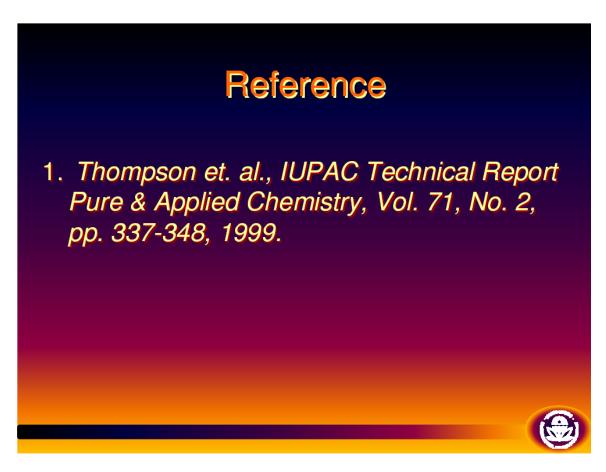

New Sampling Guidance Features

- Summary of RCRA regulatory drivers for waste sampling and testing
- Emphasis on systematic planning using the Data Quality Objectives (DQO) Process
- Sampling theory and practical methods for managing sampling error
- Sampling tools
- New sampling designs and guidance on composite sampling and "hot spot" detection

New Sampling Guidance Features (Cont.)

- Subsampling techniques
- Statistical methods and statistical tables
- Strategies for sampling heterogeneous waste
- Comprehensive examples that integrate use of the DQO Process, sampling theory, PBMS, and data quality assessment

FOR MORE INFORMATION

 - L http://www.epa.gov/epaoswer/hazwaste/test/mice.htm

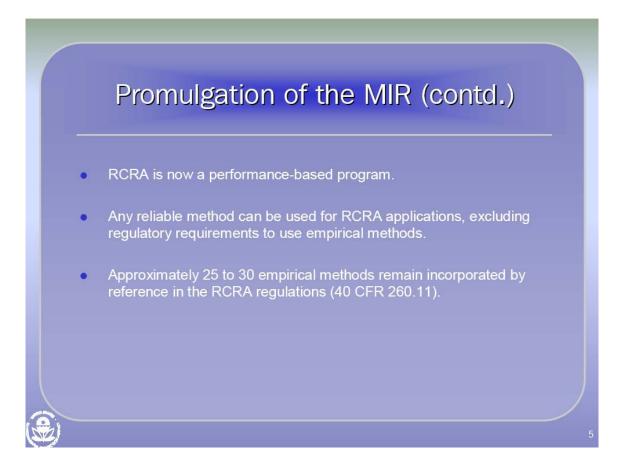

Promulgation of the Methods Innovation Rule (MIR)

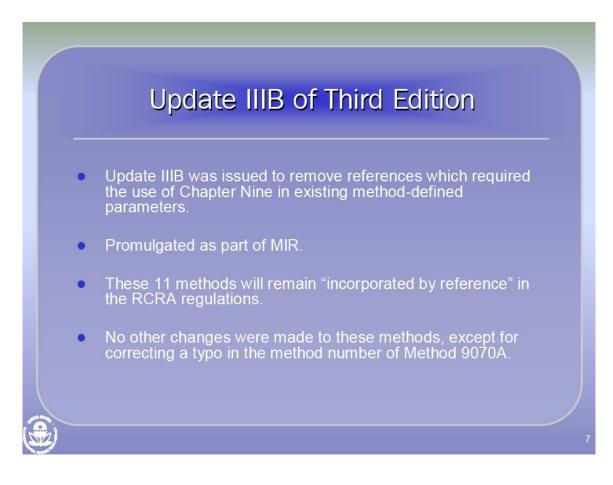

- Regulation development initiated to remove mandatory requirements to use SW-846 methods for analyses that are not method-defined parameters (empirical methods) in RCRA regulations.
- MIR proposed on October 30, 2002 (67 FR 66251).
- MIR promulgated on June 14, 2005 (70 FR 34537).

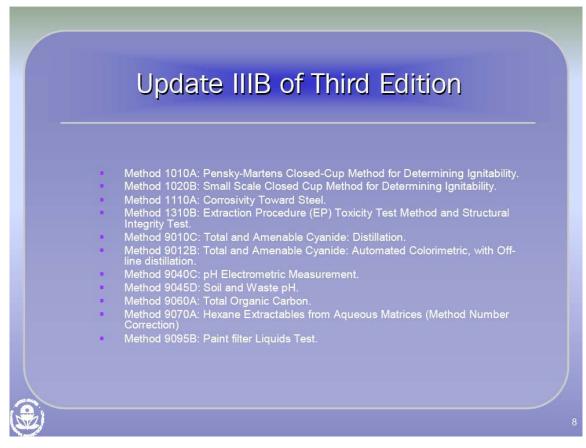

Promulgation of the MIR (contd.)

- Promulgation of the MIR eliminates the need to publish SW-846 Updates as regulations.
- SW-846 functions as originally intended, as a "guidance document."
- Updates will be put out for public comment in the *Federal Register* as Notice of Data Availability (NODA).
- Updates will be added to SW-846 through Federal Register notices modifying a guidance document.
- No change to method-defined regulations.

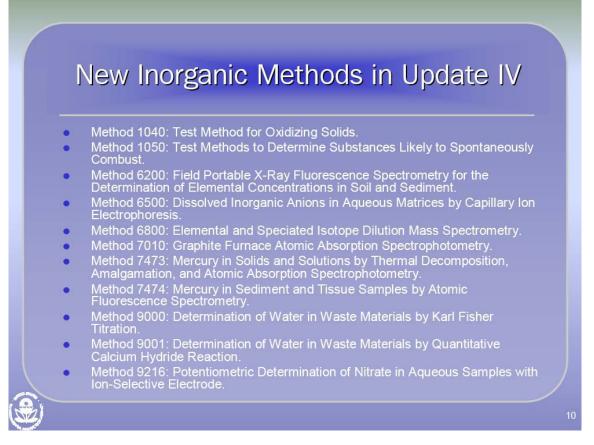

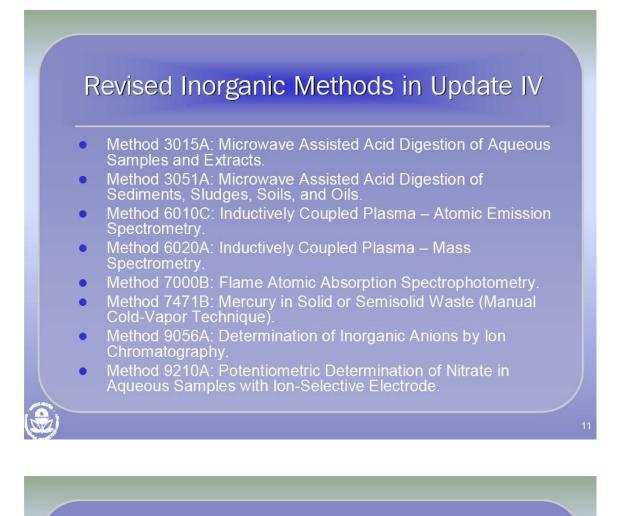

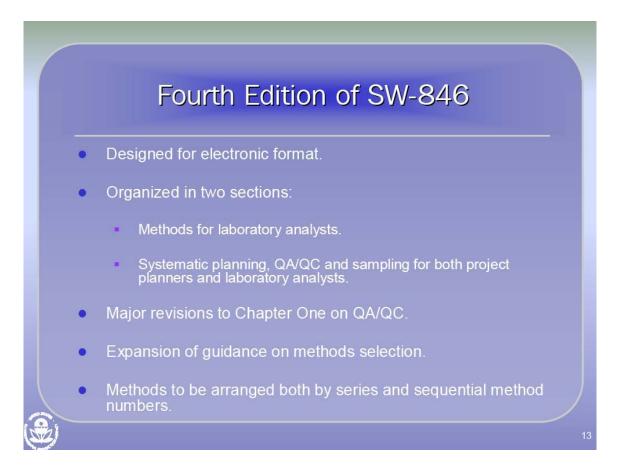

- Will be finalized as a NODA next year.
- Combines Updates IVA and IVB.
- Revisions to Chapter Three for inorganic analytes.
- 23 new methods (12 Organic & 11 Inorganic).
- 24 revised methods (16 Organic & 8 Inorganic).
- 3 OAQPS air methods added.
- 44 methods deleted (1 Organic & 43 AA methods integrated into two methods, one for FLAA and one for GFAA).
- All methods in Fourth Edition format (Style Guide on Methods Team Homepage).

Deleted Inorganic Methods in Update IV

 43 Individual Flame AA and Graphite Furnace Method AA methods integrated into two methods, Method 7000B- FAA and Method 7010-GFAA.

Fourth Edition of SW-846 Progress to Date

- Draft of Chapter One completed and distributed for Workgroup review.
- We prepared a new "Style Guide" for preparation of Fourth Edition methods based on EMMC format and distributed to Workgroup and posted it on Methods Team Website.
- All new method submissions will be in Fourth Edition format.

Fourth Edition of SW-846 Progress to Date

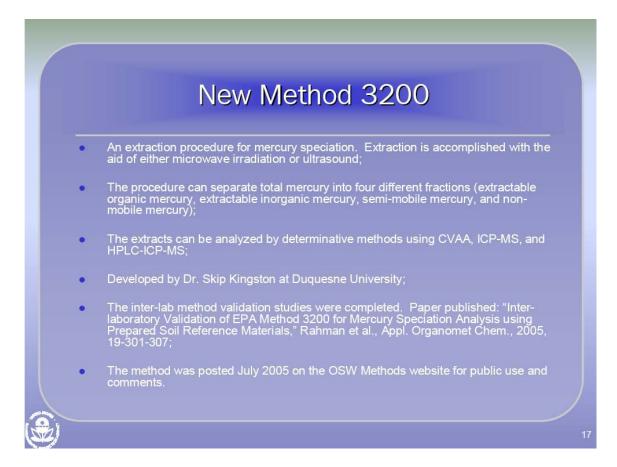

- All Third Edition methods currently being revised have been converted to Fourth Edition format including all Update IV methods and "New Methods".
- We are looking to have the Fourth Edition ready to go out for public comment in 2007.

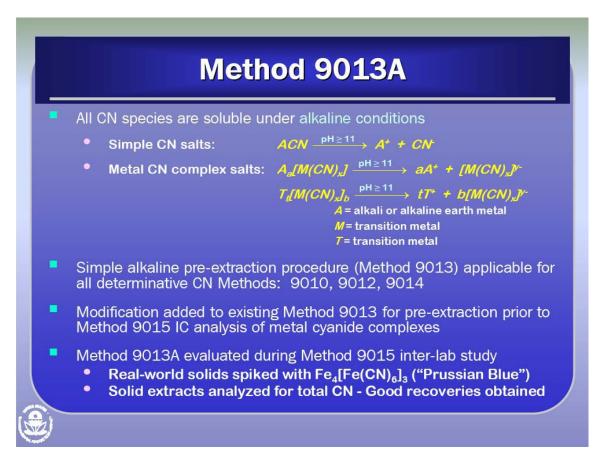

Completed New Methods for Fourth Edition

 Posted on Website under "New Methods".

- Method 3200: Mercury Species Fractionation and Quantification by Microwave-assisted Extraction, Selective Solvent Extraction and/or Solid Phase Extraction.
- Method 9013A: Cyanide Extraction Procedure for Solids and Oils
- Method 9015: Metal Cyanide Complexes by Anion Exchange Chromatography and UV Detection.

SAMPLE PREPARATION OF ELECTRONIC COMPONENTS TO ENSURE COMPLINACE WITH THE NEW ROHS/WEEE REGULATIONS

Bath, Frank and Batzke, Matthias; Retsch, Inc.

While there is some ongoing debate as to the full impact of the new RoHS/WEEE regulations, one of the major challenges is how to prepare samples of sufficient fineness for subsequent analysis and particularly if elemental species are to be accurately analyzed. Electronic boards and components present difficulties in that they are composed of a number of materials including ceramic, metal and plastics. Generally, each one of these materials requires its own different technique for size reduction, and the combination of materials onto a "PC board" presents a unique challenge for standard laboratory mills and crushers.

A technique will be presented which has been proven to be successful in reducing the size of such components to analytical fineness. The technique requires the use of a heavy duty cutting mill which utilizes a slow speed high torque motor and a specially designed cutting rotor with hardened cutting tips that can cope with the demands of the material. The cutting mill is used for initial size reduction and a second mill is used to reduce the size to analytical fineness. This mill is a vibratory disk mill or "ring and puck" mill that is commonly used in cement and mineral industries. The second process is carried out in specially designed grinding sets made of tungsten carbide which ensures that the required fineness is achieved in less than 5 minutes. For plastic only parts, a third mill may be required and depending on the required fineness, the material may need pre-chilling with liquid nitrogen or dry ice.

Data will be presented showing this process being performed on electronic boards precut to approximately 60 x 150 mm together with cell phones "as is" with only the battery removed.

NEMC 22nd Annual Conference 30 August 2006 Frank Bath

a VERDER company

OBJECTIVES

WEEE – the environmentally safe disposal of electrical and electronic devices.

RoHS – restriction in use of certain hazardous substances in these devices.

Manufacturers, sellers, recyclers and disposers of electrical and electronic devices are required to demonstrate **through analytical determinations** that the directives are being observed.

Analysis methods - XRF or ICP or ???

etsch

Affected items include:

- Large & small household appliances
- Electrical and electronic items
- Lamps and lights
- Entertainment electronics
- Communication equipment cell phones
- Electronic toys

Retsch

Electric power tools

a VERDER company

RoHS – Requirements

Places limitations on toxic substances

Regulations for heavy metals

Cadmium (Cd) Lead (Pb) Mercury (Hg) Hexavalent Chromium (Cr VI)

Regulations for 2 types brominated flame retardants

Polybrominated Biphenyl (PBB) Polybrominated Diphenyl-Ether (PBDE)

0.1% for lead, mercury, hexavalent chromium, PBB and PBDE 0.01% for Cadmium

Current situation regarding compliance.

- Confusion as to how companies should comply. Official regulations require creating homogenous sample materials from item or components where practical.
- Some advocate a "bottom up" approach where the onus is on the raw material suppliers to prove compliance and have this pass up the line to the finished product.

BUT

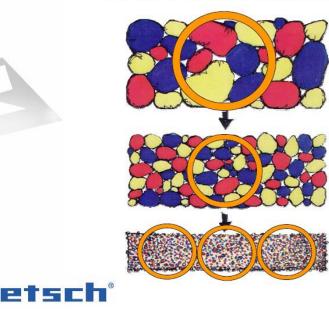

Netsch

There can be a high price for non-compliance. Example – Sony PlayStations.

Inorganic Analysis for Environmental RoHS Compliance

Zoe Grosser and Laura Thompson

PerkinElmer Analytical Sciences

ABSTRACT

The recent European directives for recycling of waste electronic products (WEEE) and reduction of hazardous materials (RoHS) that may result in environmental contamination are affecting the manufacture of electronic products on a worldwide basis. Four metals must be measured in materials complying with this regulation, including cadmium, lead, mercury, and hexavalent chromium. Additional countries are considering similar legislation and may add additional analytes of interest.

The preparation of the sample is a key component to successful measurement of the metal content and the requirements will be briefly outlined. As the RoHS rule is implemented, questions have arisen about the sampling, compositing, and analysis of materials that must comply with the rule. Total digestion versus a hot-acid leach is important for complete characterization of a waste sample, such as a battery, cable, or circuit board. The challenges of analyzing samples that are inhomogeneous will be considered.

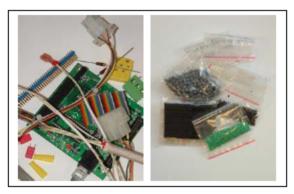

The measurement of the elements of interest using AA, ICP or ICP-MS will be discussed. Differences in analytical capability, workload, and cost of ownership will be contrasted in a variety of scenarios as guidance on technique choice.

INTRODUCTION

The European Union has put a set of directives into place to further protect the environment. The first directive regulates recycling of waste electronic and electrical equipment (WEEE). The second directive requires reduction of hazardous materials (RoHS) through the restriction of products containing $\geq 0.1\%$ Cr VI, Hg, Pb and $\geq 0.01\%$ Cd in homogeneous materials. The RoHS directive also regulates two brominated flame retardants.

Although these directives are only enforceable in Europe they are affecting manufacturing around the world. Most global companies ship to many places in the world and it would be expensive and time-intensive to segregate the merchandise manufactured for European consumption. Therefore, this regulation has far reaching effects on all manufacturing firms.

Analyses to ensure compliance with this regulation requires the digestion of a wide variety of materials. An example of the types of materials that may be observed is shown in Figure 1.

This paper will discuss sample preparation challenges and solutions. The analysis of the materials after digestion will be discussed and the choice of inorganic analysis technique explored.

EXPERIMENTAL

Samples of old electronic components were obtained from various sources. One wire cover and clip sheath were reported to be undergoing a manufacturing change because of RoHS non compliance and was included in the sampling. Raw plastics were obtained from a manufacturer in China.

Samples were digested using the MultiwaveTM 3000 (Anton Paar). Electronic components were cut into small pieces and the pieces mixed thoroughly before weighing approximately 0.1 gram into a quartz or PTFE digestion vessel. Electronic components were digested with 6 mL HNO₃/2 mL H₂O₂/1 mL HF. Raw plastics were digested with 9 mL HNO₃. Samples were digested following a 45 min power program:

- Ramp from 0-600 W for 5 min, hold for 15 min
- Ramp from 600-1400 W for 5 min, hold for 20 min

Digestates were transferred and diluted to 50 mL with ASTM Type I water.

Analysis was performed using inductively coupled plasma optical emission (ICP-OES) and Flame Atomic Absorption (FAAS). Default conditions were used for the analysis of Pb and Cd using the AAnalystTM 400.

The Optima™ 5300 ICP-OES was used for a full, suite of elements, including mercury.

- Axial mode used for elements where increased sensitivity was required, such as Sb, As, Be, Cd, Cr, Cu, Pb, Hg, Se, etc.
- · Radial mode used for elements expected at higher concentrations, such as Ba, Mg, Mn, etc.
- Low-flow GemCone Nebulizer

- · Cyclonic spray chamber
- On-line addition of internal standard

Total analysis time was approximately 3 minutes per sample.

RESULTS AND DISCUSSION

Digestion of samples can be a challenge due to the homogeneity of the sample. The regulations are unclear on whether each component or subassembly should be sampled or whether a composite more clearly represents the product for regulation. Many companies are taking their best guess at how to interpret the regulation and comply with testing.

Some of the samples tested here were clearly homogeneous, such as the raw plastic material and yellow plastic sleeves. Some were not homogeneous, such as the circuit board and ribbon cable. With more sophisticated grinding tools the homogeneity of the sample for replicate digestions could have been improved.

Microwave digestion proved satisfactory for the wide range of materials digested. Increased temperature and pressure ensure that resistant components are solubalized and the closed system retains the mercury in solution. The acid ratio was adjusted on the least homogeneous sample until a clear digest was obtained. This program was used for the rest of the electronic component samples.

Inorganic analysis using FAAS, ICP-OES, and inductively coupled plasma mass spectrometry (ICP-MS) techniques were evaluated for possible analysis of samples. AA requires the lowest initial investment and is simple to use. However, it measures a single element at a time which can be slow if a large number of elements need to be measured. It also requires a separate analysis for mercury using the cold vapor technique. ICP-OES requires a moderate initial investment and is a fast multielement technique. Mercury can be included in the multielement list of analytes and determined at the same time. Since additional elements increase the analysis time by a negligible amount, elements that may be of interest in the future can be monitored. ICP-MS requires a higher initial investment and also provides a fast multielement technique. It provides lower detection limits for the use of a smaller sample size or compliance with lower limits. Like ICP-OES, mercury can be included in the suite of analytes and additional elements can be included for screening.

The concentration in solution after digestion may be several ppm, indicating that ICP-OES may be the best choice. Axial configuration ICP-OES will be evaluated and compared with flame AA, with similar concentration range strengths. Table 1 shows a recent draft ISO standard listing guidelines for sample preparation, both mechanical and digestion, and analysis. It seems logical to measure total chromium first and only measure chromium VI if the limit is exceeded with the total amount.

Table 6: AA and ICP-OES Analysis Compared (mg/kg in the solid)

ND: not detected

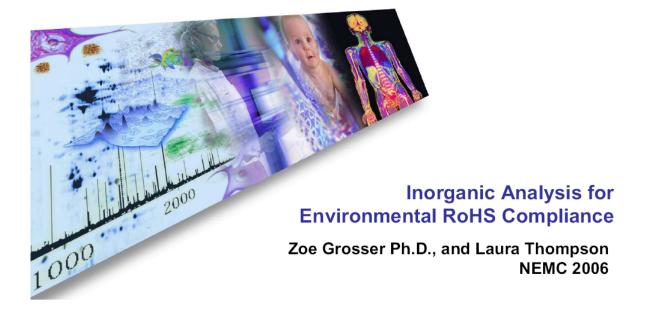

The results obtained with the two techniques compared favorably. ICP-OES took approx 3 minutes for the analysis of 18 elements AA took about 15 seconds for the analysis of 1 sample for 1 element, after calibration. ICP-OES can include Hg in a multielement analysis if the sample preparation preserves Hg. If more than 8 elements are being determined, ICP-OES is the faster technique. Many laboratories will find ICP-OES to be the more suitable technique for this analysis because of the considerations mentioned and the versatility of the technique for other projects that may require metals analysis.

CONCLUSION

Microwave digestion is an excellent sample digestion technique for RoHS compliance because of sample variability tolerance and the ability to retain volatile elements. Digestion time is predictable and reduced below hot plate digestion time due to high temperature/pressure.

ICP-OES provides several benefits for the analyses of RoHS matrices including multielement capabilities to provide rapid information on a variety of elements, suitable detection limits, and wide dynamic range to meet the needs of potentially diverse samples. Analysis of a variety of samples demonstrates repeatability, spike recovery, and good precision for materials containing different levels of analytes of interest and other elements that may be needed for informational purposes.

European Union (EU) Regulations

- Waste Electrical and Electronic Equipment (WEEE) directive
 - In effect in the EU since August 2004
 - · Requires manufacturers to take back and recycle electrical products
- Restriction of Hazardous Substances (RoHS) Legislation
 - Applies to the entire EU from July 2006
 - Bans products containing ≥ 0.1% Cr VI, Hg, Pb and \geq 0.01% Cd in homogeneous materials and regulates two brominated flame retardants

Appropriate sample preparation and analysis techniques must be performed to demonstrate compliance

Who will need to perform these analyses?

- Large manufacturers with laboratories
- Contract laboratories
 - Environmental
 - Materials testing

Anyone who plans to sell their product in the European Union

Compliance with RoHS

Page 3

- As of July 1, 2006 electrical equipment sold in the EU must comply with these regulations
 - Producers will need to be confident their products comply, but the directive does not provide guidance
 - · Analysis of every component would be expensive
 - But analysis of assemblies or finished materials might give false confidence if compared to a limit determined on a component basis (homogeneity is also a challenge)
 - Large manufacturers have exhaustively considered their products and suppliers and developed implementation plans with the limited information available

Company/ Specifications	Cd	Pb	Hg	Cr+6	Packing Material	Ni	Reference

Objectives of this Paper

- Evaluate inorganic analysis techniques for a variety of materials and business situations
 - Digested and analyzed a range of electrical components, assemblies and raw materials
 - Raw materials that will be used to produce cable coverings and other electrical components
 - Assemblies and components that represent a variety of colors and materials

- Develop a sample preparation technique to meet requirements of RoHS regulations
 - Diverse sample matrices
 - Total dissolution necessary
 - Limit contamination
 - Prevent volatile element loss (Hg, Cd, Pb)

Sample Variety

Microwave versus Conventional Digestion

- 1. Fast, about 30 40 minutes
- 2. Digestion Temp. up to 300 °C
- 3. Minimized contamination
- 4. Can use HF, H₂SO₄, & H₂PO₄
- 5. No losses of volatile elements such as Hg, As, Sb & Se etc.
- 6. Pressures range up to 80 bar
- 7. Suitable for organic as well as inorganic materials
- 8. Fully automatic, user supervision not required

1. Larger Sample quantity

- 2. Longer digestion time: 30 min. to 2 hours
- 3. Total Digestion can be difficult
- 4. Digestion temperature limited to ~130 °C
- 5. Serious corrosive acidic fumes, contamination & operators' health issues
- Corrosive to lab. environment and instruments
- 7. Loss of volatiles possible
- 8. Close supervision is normally required, to prevent charring of samples

Page 9

Microwave Digestion

Microwave digestion chosen

- Multiwave 3000 digestion system
- · 50 mL ceramic-jacketed Teflon vessels
- 8-position Rotor with full pressure control at each position
- 1400 W maximum power program

Microwave Digestion

- Approximately 0.1 g of each sample was weighed and transferred to the digestion vessel
- Reagents were added to the vessels
 - Plastics: 9 mL HNO₃
 - Components and assemblies: 6 mL HNO $_3/2$ mL H $_2O_2/1$ mL HF
 - Samples were digested following a 45 min power program
 - Ramp from 0-600 W for 5 min, hold for 15 min
 - Ramp from 600-1400 W for 5 min, hold for 20 min
 - Digestates transferred and diluted to 50 mL with DI H₂O

Inorganic Techniques

PerkinElmer

- Atomic Absorption (AA)
 - Low initial investment
 - Simple to use
 - · One element at a time can be slow
 - Separate analysis for mercury
- > ICP-OES
 - · Moderate initial investment
 - Fast multielement technique
 - · Can include mercury in the analysis
 - · Can screen for other elements that may be of interest in the future
- > ICP-MS
 - Higher initial investment
 - Fast multielement technique
 - Lower detection limits for use of smaller sample size or compliance with lower limits
 - · Can include mercury in the analysis
 - · Can screen for other elements that may be of interest in the future

Page 13

Choice of Technique

- Concentrations in the solid may range up to 1000 ppm, yielding up to several ppm in solution
- ICP-MS can measure the elements of interest at once, but dilutions may be required to avoid contaminating the instrument
- Flame AA or axial ICP-OES will provide a sufficient detection limit and good linear range
- Axial ICP-OES can measure all the elements of interest in one run: Pb, Cr (total), Cd, and Hg

Axial ICP-OES will be evaluated with comparison to flame AA

- > Optima 5300 DV
- Axial mode used for elements where increased sensitivity used, such as Sb, As, Be, Cd, Cr, Cu, Pb, Hg, Se, etc..
- Radial mode used for elements expected at higher concentrations, such as Ba, Mg, Mn, etc..
- Low-flow GemCone Nebulizer
- > Cyclonic spray chamber
- > On-line addition of internal standard
- > Total analysis time approximately 3 minutes per sample

Page 27

Comparison with Flame AA

- > Analysis compared with flame AA for Pb and Cd
- ICP-OES took approx 3 minutes for the analysis of 18 elements AA took about 15 seconds for the analysis of 1 sample for 1 element, after calibration
- ICP-OES can include Hg in a multielement analysis if the sample preparation preserves Hg
- If more than 8 elements are being determined, ICP-OES is the faster technique

- Microwave digestion is an excellent sample digestion technique for RoHS compliance
 - Sample variability tolerance
 - Volatile element retention
 - Reduced digestion time due to high temperature/pressure
- > ICP-OES provides several benefits for the analyses of RoHS matrices
 - · Multielement to provide rapid information on a variety of elements
 - Suitable detection limits and wide dynamic range to meet the needs of a potentially diverse sample variety
- Analysis of a variety of samples demonstrates repeatability, spike recovery, and good precision for materials containing different levels of analytes of interest and other elements that may be needed for informational purposes

MODERN INTERFERENCE CORRECTION INCLUDING CELL-BASED TECHNOLOGY FOR ICP-MS ENVIRONMENTAL ANALYSES

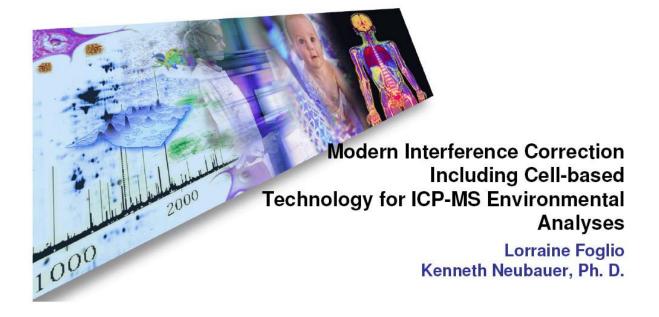

Foglio, Lorraine and Neubauer, Kenneth; PerkinElmer Analytical Sciences

ICP-MS has become increasingly popular for environmental analyses because of the low detection limits and ability to measure a large number of elements very quickly. In addition, the ICP-MS offers the ability for isotope ratio measurements and is an excellent detector for speciated inorganic analyses.

Interferences are problematic in most instrumental analytical techniques. Depending on the matrix, interference effects may be mild or severe. In most cases, some type of compensation is available to minimize the effect of interferences. The nature of interferences problematic in ICP-MS will be discussed. The historical forms of interference compensation will be described.

The development of cell-based technology to correct interference problems in this technique will be outlined and the corresponding benefits described.

- > Most analytical techniques have interferences
- > Usually can be understood, minimized and controlled
- Talk will discuss the interferences found in the use of ICP-MS for environmental analysis
- Mechanisms of interferences and methods of correction will be discussed
- > Update on cell usage for US environmental methods

Interferences in ICP-MS

- Caused by something in the sample not present in the Calibration Blank and Standards..... leads to incorrect results.
- Physical, Bulk Property of Sample
 - Viscosity
 - Matrix
 - Space Charge
- Spectral, Atomic or Molecular Content of Sample
 - Atomic Isotope
 - Molecular Polyatomic Ion

Page 3

Physical Interference Viscosity

- > Common in ICP emission and ICP-MS
 - Sample Different from Calibration Solutions
 - Surface tension
 - Viscosity
 - Aerosol transport effects
 - droplet formation by nebulizer
 - droplet size selection in spray chamber
- Internal Standardization
 - · Can compensate for Physical Interferences

PerkinElmer

Analytes are Ratioed to Internal Standard recovery

Element	Mass
Li	6
Sc	45
Ge	72
Y	89
Rh	103
In	115
Tm	169
Lu	175

Frequently Employed as Internal Standards

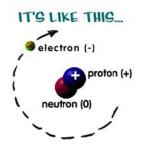

EPA Methods Require at Least 5 Internal Standards

Page 5

Physical Interference Matrix

- > Energy reduced in plasma sometimes called "Plasma Loading"
- > Readings are generally suppressed
- Can be minimized
 - Keep dissolved solids below 0.1%
 - Robust plasma conditions
- Use internal standards matched by ionization potentials as well as mass.
 - Se = 9.75
 - Zn = 9.34
 - Ge = 7.90
 - In = 5.79

Spike Recovery vs. Internal Standard Element

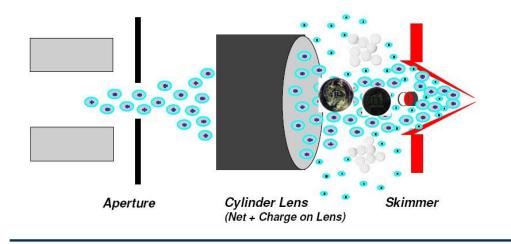

Element	Internal Standard	Spike Recovery
Zn	ln	76.2
	Ge	103.1
As	ln	84.5
	Ge	96.3
Se	In	79.3
	Ge	83.2

Page 7

Physical Interference Space Charge Effect

- > High mass matrix elements can suppress low mass analyte signals
- Like Bowling Balls and Ping Pong Balls
- EPA Methods require the use of at least 5 internal standard spread across the mass range to correct for Space Charge Effects.

Detection of Physical Interferences

- Spiked samples
- Check Reference materials
- > Non-linear response after dilution indicates probable interference
- Poor "Recovery" of Internal Standard Elements
- > Or, just assume they are always present

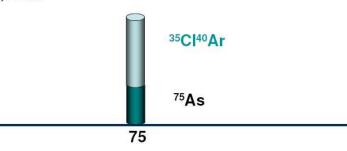

Page 9

Spectral Interference Atomic and Polyatomic Mass Overlaps PerkinElmer

Samples containing particular elements may have atomic isotope overlaps or form polyatomic molecular ions.

The most common are:

- Samples with High Metallic content
- Argon-forming or ArX where X=O, CI, P, S, etc.
- Oxides: MoO, TiO, CaO
- Dimers: Ar₂, N₂, O₂, S₂, P₂
- Hydrides: ArH, BrH
- Hydroxides: CaOH, ArOH

Some spectral interferences found in common matrices

Interference	Analyte
⁴⁰ Ar	⁴⁰ Ca
⁴⁰ Ar ¹⁶ O, ⁴⁰ Ca ¹⁶ O	⁵⁶ Fe
⁴⁰ Ar ¹² C, ³⁵ Cl ¹⁶ O ¹ H	⁵² Cr
⁴⁰ Ar ¹³ C , ⁴⁰ Ar ¹² C ¹ H	⁵³ Cr
³⁵ Cl ⁴⁰ Ar	⁷⁵ As
⁴⁴ Ca ¹⁶ O	⁶⁰ Ni
⁴⁰ Ar ²³ Na	⁶³ Cu
³⁵ Cl ¹⁶ O	51 V
⁸¹ BrH	⁸² Se

Page 11

Spectral Interference Correction Options

- Isobaric Correction Equations
- > Cold Plasma: Reduces argon-based interferences in Simple Matrices
- > High Resolution MS: Can resolve some interferences nicely
- Collision Cell
 - Uses passive fixed potential rods (multi-poles)
 - Dependent on Kinetic Energy Reduction by Passive Collisions with Inert Gas

Dynamic Reaction Cell

- Uses second Active Quadrupole
- Uses Reactive Gas to "Chemically Remove" Interferences

Spectral Interference Atomic Isobaric Overlap

Isobaric Overlaps

· Be aware of what is in your samples when selecting isotopes

Element	46	47	48	49	50
Ca	0.004		0.187		
Ti	8.0	7.3	73.8	5.5	5.4

Percent Abundance

Page 13

Handling the Interference Isobaric Correction Equations

- Built into the software to automatically correct for atomic isobaric overlaps
- Similar to IECs in ICP emission spectroscopy
- Except isotope ratios don't change, they are fixed in nature

What's going on at Mass 51? Polyatomic Interference

Example: ³⁵Cl¹⁶O interference on ⁵¹V at mass 51 But: ³⁷Cl¹⁶O forms proportionally at mass 53

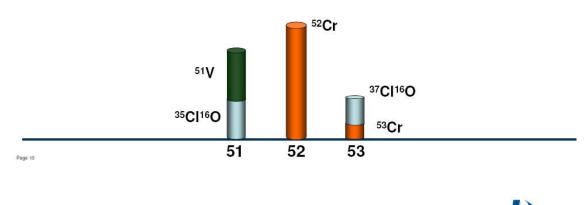

⁵¹V = mass51 - a³⁵Cl/a³⁷Cl* mass53

PerkinElmer

⁵¹V= mass51 - 3.127*CIO53

But, Cr is also at mass 53, so must correct for Cr on CIO53!

⁵¹V = mass51 - 3.127*(CIO53 - (0.113*Cr52))

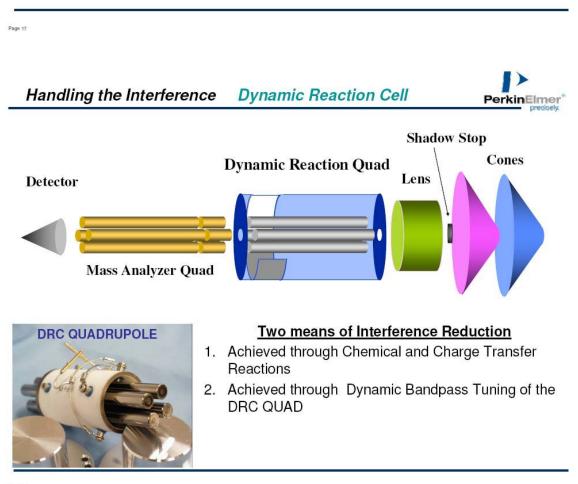

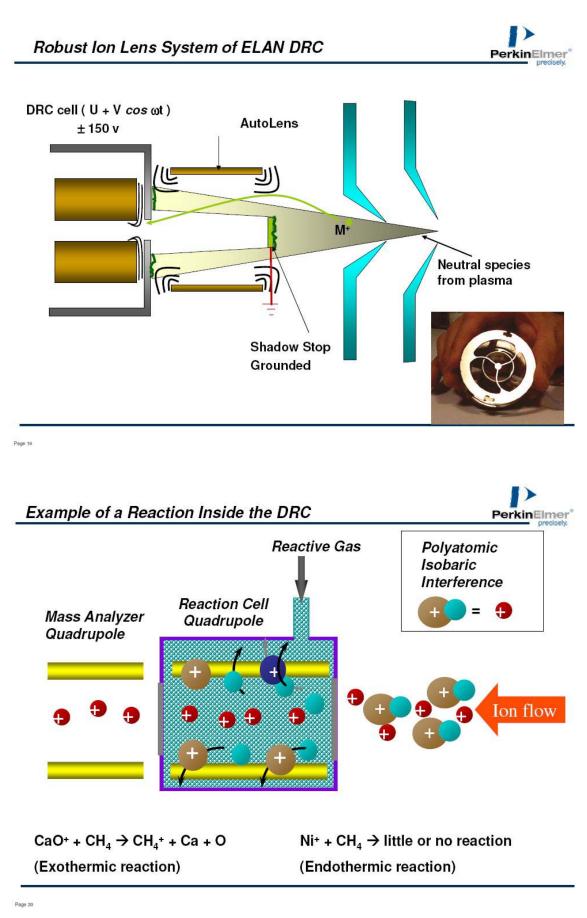

Collision Cells Trap and Retain Interfering Species PerkinElmer Analytical Detector Quad Energy Cell Barrier Plasma Off Axis E lon Lens 100 100% Intensity Intensity 5% Interference removal at mass 52 Cr ArC ArC Page 16

Collision Cell Limitations

- Relies on Probability of Collisions with Inert Gas and Kinetic Energy
 Discrimination (KED)
 - Analyte Signal Loss Severe With KED
 - All ions lose energy, including analytes of interest
 - Analyte loss of greater than 95% not uncommon
 - All Collision Cells require the use of a shielded torch
 - Cannot make analytical use of polyatomic ions created in the cell (AsO+)
 - Mass Dependant: Analytes with energy less than the KED set point will be lost
- Ions are not removed All ions are free to recombine, forming new and unpredictable molecular interferences
 - Reactive gases can generate new interferences that cannot be removed from the cell (passive guide only-non scanning) so they cannot use reactive gases in multi-element determinations.
- · Cannot make analytical use of polyatomic ions created in the cell (AsO+)

Handling the Interference Dynamic Reaction Cell

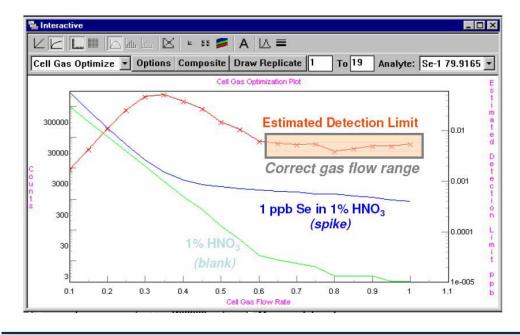

- The DRC is pressurized by a reaction gas. Any gas can be used based on its ability to:
 - React with the analyte
 - Dissociate polyatomic species
 - Electron or proton transfer
 - React with the analyte
- Dynamic bandpass tuning of the quadrupole ejects all unwanted reaction products and removes them from the cell
- Only analyte ions are focused through both the reaction cell and the analytical quadrupole

Page 21

DRC Mode Optimization for Selenium

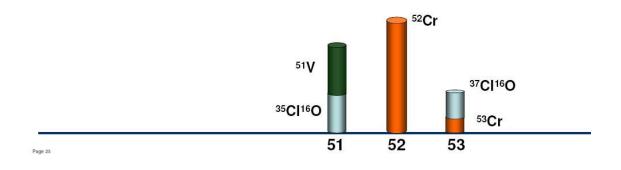

Typical Cell Gas Optimization Curve

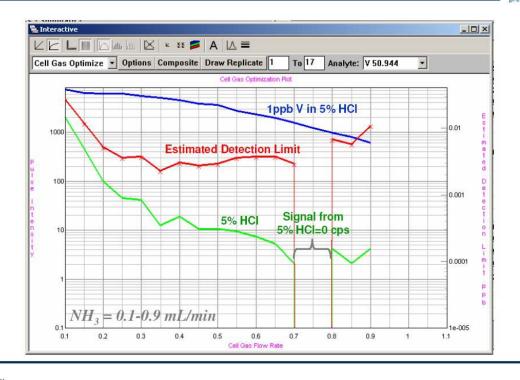

PerkinElmer

- Problem: ³⁵Cl¹⁶O⁺ occurs at the same m/z as the major V isotope
- Goal: Eliminate CIO+ interference
- > How
 - Use a Dynamic Reaction Cell
 - Reaction Gas = NH₃
 - Matrix = 5% HCl
 - Spike = 1 μg/L V in 5% HCl

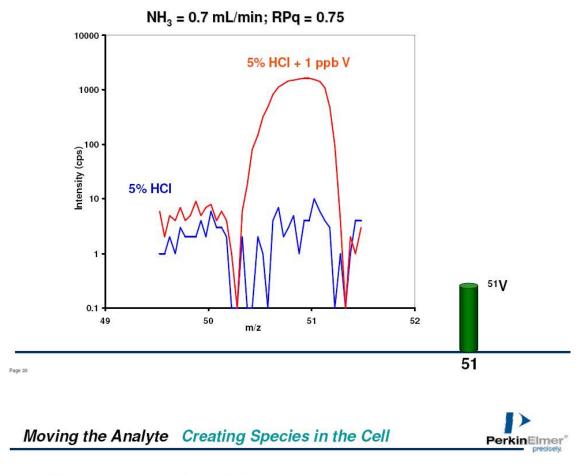

Cell Gas Optimization

- > Move analyte away from the interference
 - Lower backgrounds
 - · Possible because of controlled chemistry
- \succ Many times this can be accomplished using O₂ as reaction gas
 - ⁷⁵As into ⁹¹AsO

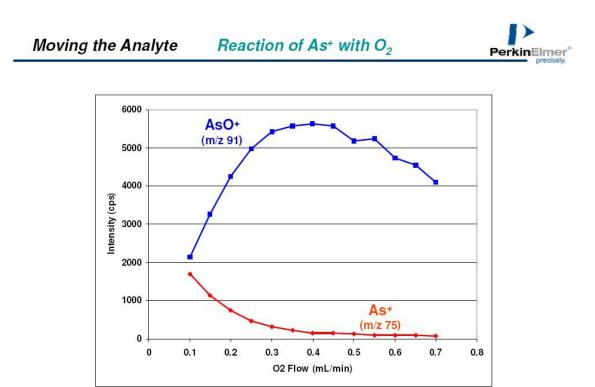

Chlorides

- ArCl⁺
- CaCl⁺

> Examples of chloride or calcium containing matrices

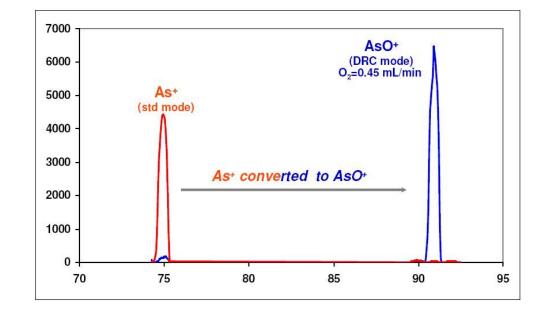

- Environmental
 - Wastewater, seawater, brines, soil digests
- Clinical
 - Urine
- Semiconductor
 - High purity HCI
- Isobaric Correction Equation for Standard ICP-MS
 As = As75 3.127*{ArCl77 (0.815*Se82)}

Page 27

DRC Advantages

PerkinElmer

- Minimal Sensitivity Loss
 - Collisions are not the primary interference removal pathway
 - DRC promotes analyte movement through the cell with AFT
 - No kinetic energy barriers are set
- Reactions are predictable
 - Interference removal follows predictable chemistry
 - Not dependant on interference concentration
- Interference ejected
 - Dynamic bandpass tuning ejects interferences and does not allow them to reach the analytical quadrupole

DRC Modes of Operation

PerkinElmer

Dynamic Reaction Cell Mode

- · Cell is pressurized with continuous flow of reaction gas
- · Bandpass is optimized for elimination of interfering species

Standard Mode

- · Cell is vented (no reaction gas)
- Operates as a standard ELAN with the advantage of lower noise

Mixed Mode Method

- DRC and standard mode elements are grouped by the software and automatically run in the same method
- 30 second delay switching modes

Page 31

Method 200.8 Overview

- Version 5.4, May 1994
 - Available EPA/600/R-94/111
- > Applicable Elements
 - Al, Sb, As, Ba, Be, Cd, Cr, Co, Cu, Pb, Mn, Hg, Mo, Ni, Se, Ag, Tl, Th, U, V, and Zn
- Applicable Matrices
 - · Ground waters, surface waters, drinking waters
 - · Wastewaters, sludges, soils
 - With sample prep contained in method

Method	200.8	for	SDWA	۱
--------	-------	-----	------	---

- Approved for all 12 primary contaminants from Safe Drinking Water Act
 - As, Ba, Be, Cd, Cr, Hg, Pb, Ni, Cu, Sb, Se, and TI
 - Must meet <1 NTU rule to avoid sample prep
- > First time a *single* method may be used to determine all 12 primary contaminants
 - Allows reduction in monitoring costs - Reduced analysis and prep costs
- > Although not primary contaminants, Ca, Fe, Na, K, and Mg may be monitored by ICP-MS
- > Not Approved for "Cell" use. Can use a DRC or DRC-e version in Standard mode.

Summary

- Cell not necessary for routine drinking water analysis, but can help avoid unexpected levels of interferences
- > Cell may be useful for complex wastewater, soil, or waste samples
 - · Depending on detection limit required
 - Depending on matrix (potential interferences)
- Cell provides
 - · A tool for Interference removal
 - Cell use and standard mode can be used in same run
 - Two gases can be used
 - DRC provides controlled chemistry
 - DRC provides opportunity to use reaction products such as AsO to gain enhanced sensitivity
 - DRC easy to set up, reproducible day-to-day
 - · DRC does not need to be cleaned

Determination of Total Cyanide without Distillation

William Lipps

Product Line Specialist, ACA Products, OI Analytical

ABSTRACT

Determination of total cyanide by existing EPA methodology requires either manual or on-line distillation from a sample acidified with a strong acid. Serious problems have been recognized with these traditional methods. This paper presents interferences associated with EPA approved methods and describes a non-distillation method based on segmented flow on-line UV digestion-gas diffusion with amperometric detection. This technique eliminates the need for time-consuming distillations, has a throughput of up to 30 samples per hour, and is virtually interference free.

INTRODUCTION

The EPA has defined "total cyanide" as the amount of cyanide ion liberated by distillation with a sulfuric acid – magnesium chloride solution followed by either colorimetric, titrimetric, or ion selective electrode measurement. The high heat and low pH of the distillation process have been demonstrated as causing low reproducibility and questionable accuracy, as well as being known to produce both false positive and false negative results depending upon the sample matrix. Table 1 lists current EPA approved methods for the determination of total cyanide in wastewater analysis along with their known interferences.

MethodologyReferenceSample ProcessingDeterminative StepListed InterferenceManualEPA 335.2The cyanide as hydrocyanic acid (HCN) is released from cyanide complexes by means of a reflux-distillation absorbed in a scrubber containing sodium hydroxide solution.The cyanide as absorbing solution is then determined by volumetric titration using silver nitrate or colorimetrically using distillation.1. Oxidizing agents ca destroy cyanides during then determined by storage. Sulfide can complex with cyanide in sample or distillate. Fatt acid procedure.

*These interferences must be eliminated prior to analysis.

Distillation

In the absence of interference, simple cyanides such as HCN, KCN, and NaCN are determined readily by each of the determinative steps, however, to determine "total" cyanide metal cyanide bonds must be broken and cyanide separated to produce simple cyanide. In all the approved EPA methodology this is accomplished by distillation from acid solution. Although distillation is assumed to eliminate, or at least minimize, most interferences the high temperature and strong acid solutions can potentially introduce significant positive or negative bias.

Compound	Description of Interference
Oxidizers	React with CN during distillation causing negative bias.
Sulfide	Distills over and reacts with CN is the alkaline absorber solution to form thiocyanate, causing a negative bias
Oxidized Sulfur Compounds	React with CN in absorber solution to form thiocyanate, causing negative bias.
Thiocyanate	Decomposes to oxidized sulfur compounds, which react with cyanide in the absorber solution to form thiocyanate causing a negative bias.
Thiocyanate + Nitrate	Thiocyanate decomposes forming cyanide, causing a positive bias.
Sulfur Dioxide	Sulfur dioxide in the absorber solution can react with chloramine T during the colorimetric step, resulting in a negative bias.
Nitrate or Nitrite + Organics	Can react to form cyanide causing a positive bias.

Thiocyanate and sulfide are commonly occurring compounds in industrial waters and wastewaters and are the most common and significant interferences in distillation-based cyanide methods. While there are ways to remove sulfide, there are no adequate solutions for the removal of thiocyanate prior to analysis. The assumption that thiocyanate interference can be compensated for by the analysis of "Total Cyanide including Thiocyanate" and subtracting thiocyanate determined by a separate analysis depends on the accuracy of the cyanide measurement made in the presence of thiocyanate. Because thiocyanate can produce both positive and negative interferences, without an accurate analysis of each matrix, one can never be sure whether to add or subtract.

Development of a Distillation-Free Method for the Determination of Total Cyanide

Recognizing that most interferences in accepted total cyanide determination methods stemmed from the distillation step that was supposed to eliminate interferences, researchers developed a distillation-free total cyanide method based on segmented flow, on-line UV digestion, and gas diffusion with amperometric detection.¹ This novel method quantitatively liberates most strong metal cyanide complexes and accurately measures total cyanide from 0.002 to 5.00 mg/L at a rate of two minutes per sample. The method is available from OI Analytical as Total Cyanide by UV-Digestion Amperometric Detection.

Description of Instrumentation and Procedures

A Flow Solution FS 3100 Analyzer (OI Analytical, College Station, TX, USA) is configured for total cyanide according to the diagram in Figure 1.

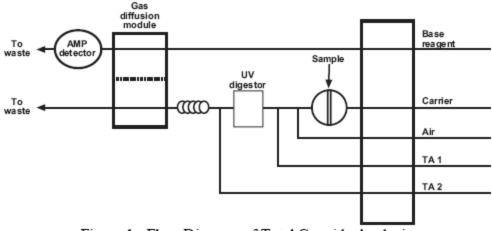

Figure 1: Flow Diagram of Total Cyanide Analysis

Two hundred micro-liters of sample is introduced by the carrier solution into an acid stream (Total Acid Reagent 1 or TA 1) and segmented with air to prevent excessive dispersion. After a mixing coil the sample is irradiated at 350 nm dissociating cyanide complexes but preventing the decomposition of thiocyanate and other side reactions. After exiting the UV digester, the sample is mixed with another reagent (Total Acid Reagent 2 or TA 2) that contains a complexing agent that can remove up to 50 mg/L sulfide. The stream then passes under a gas diffusion membrane where the HCN formed passes through into an absorber solution of dilute sodium hydroxide. The amperometric detector quantitatively determines cyanide in the absorber solution. Figures 2 through 5 illustrate the performance of the method.

Sulfide	Not tested	0.198	0.120	0.189

Table 5:	Cvanide Interfe	rence during Distillation	1 Compared to OI Method
		0	

There are no known spot tests to detect thiocyanate, sulfite or thiosulfate accurately at 20 mg/L so no treatment was applied to these samples. All samples were spiked at the Drinking Water Maximum Contaminant Level of 0.2 mg/L Cyanide. Data indicates that cyanide can co-exist in solution with oxidizers such as sulfite and thiosulfate. Data also indicates a potential issue that could arise from not detecting cyanide when it is actually present.

	Thiocyanate (mg/L)	Nitrate (mg/L)	Cyanide Found (mg/L; sulfamic acid not added)	Cyanide Found (mg/L; sulfamic acid added)
Sample 1	50	100	12.0	3.4
Sample 2	6	127	2.00	0.26
Sample 3	9	40	2.80	0.16

Table 6: Distillation Interferences That Cause False Positives²

Even though sulfamic acid is recommended in the methods to eliminate nitrate interference, cyanide was still detected in samples that did not contain cyanide.

Table 7: Other Interferences that Cause False Positives by Distillation³

Compounds Added	Cyanide Found
Ammonia, Bleach, Ascorbic Acid	Detected
10 g Sodium Nitrite + 10 mmol i-propanol	112 mg/L
10 g Sodium Nitrate + 10 mmol i-propanol	14.2 mg/L

Nitrogen compounds, common in most wastewaters, can react with organic matter during the distillation process and create cyanide.

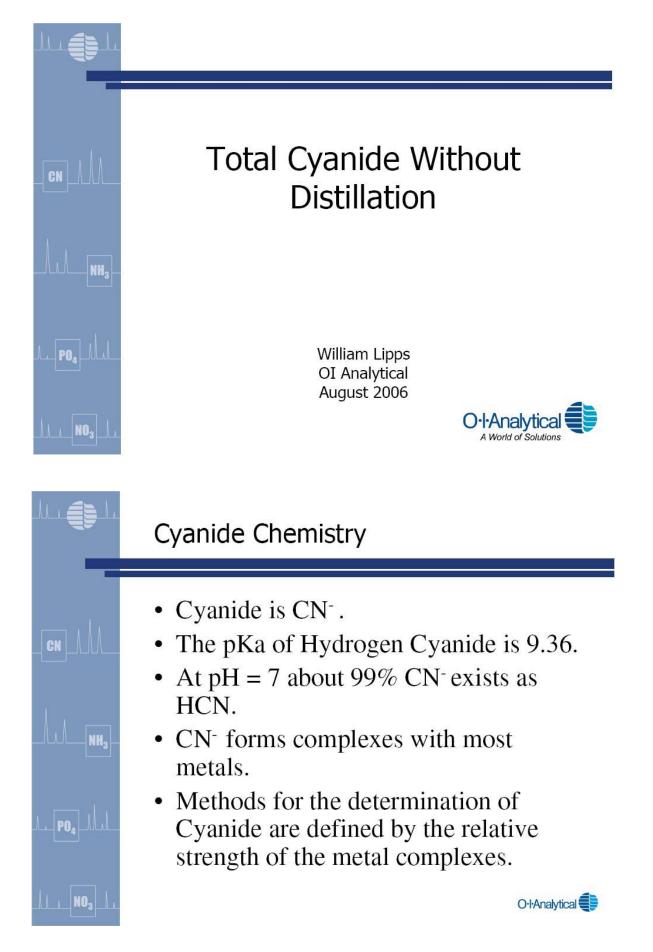

CONCLUSIONS

Approved total cyanide methods requiring a preliminary distillation step often produce unreliable data in complex real world samples. A method developed by OI Analytical, "Total Cyanide by On-Line UV Digestion Amperometric Detection", solves most interference problems and produces reliable data in the presence of known interferences.

Although the method has not been approved by EPA, it is still advantageous to analyze cyanide by a method known to produce correct results. Analyzing strictly for compliance purposes can result in serious errors including potential under-reporting when cyanide is actually present or in over-reporting when cyanide is not even there.

NO₃

• Alkali metals form ionic bonds with the CN molecule.

Sources and Uses of Cyanide

- Cyanide is produced in nature by certain bacteria, and found in numerous foods and plants.
- Organic Cyanide compounds are called Nitriles. (these are not very hazardous)
- Hydrogen Cyanide is a product of Combustion and is found in:
 - Automobile exhaust (single largest source of HCN pollution)
 - Cigarette smoke
 - Burning of plastic (house fires, etc.)

Cyanide Speciation

- The "species" of Cyanide present in a water sample is determined by:
 - pH

NH₂

PO.

LL NO₃

- Presence of Oxidizers
- Presence of Transition metals (and which ones)
- Presence of sulfur and sulfur compounds

Homeland Security

Building Environmental Laboratory Capability in Support of Emergency Response

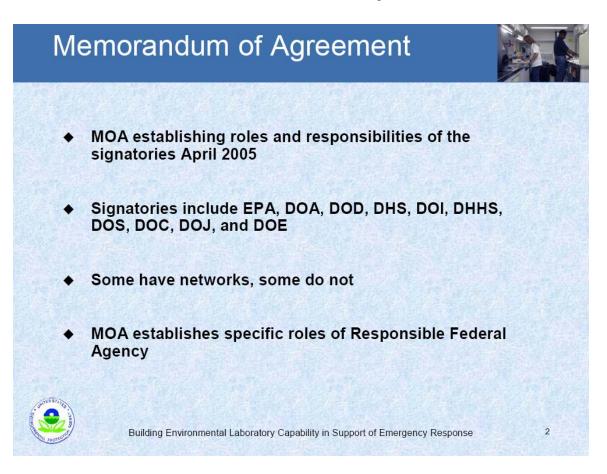

NEMC Presentation August 29, 2006 By Allan Antley

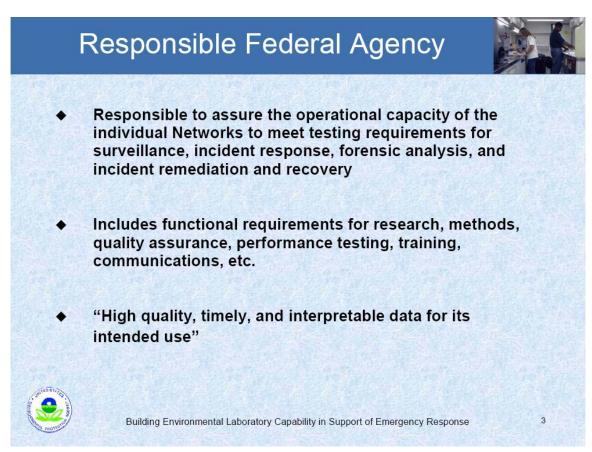

Brief History of the Integrated Consortium of Laboratory Networks

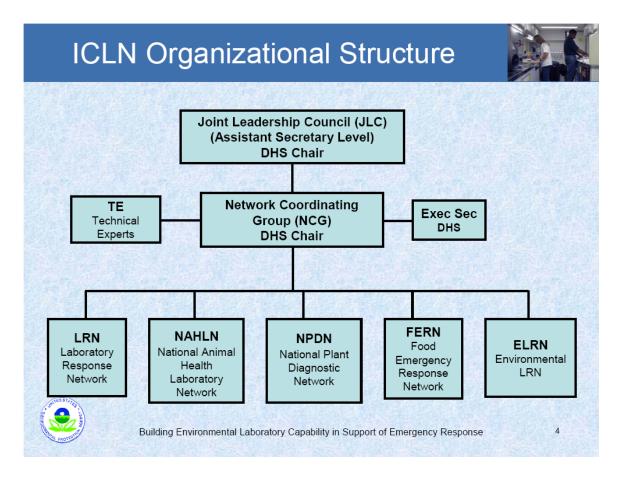

- White House Homeland Security Council involvement began in November 2004
 - Gathered agencies involved, endorsed independent network involvement, and recognized the benefits gained from creating a collaborative alliance
- Vision: A U.S. homeland security infrastructure with a coordinated and operational system of laboratory networks that provide timely, high quality, and interpretable results for early detection and effective consequence management of acts of terrorism and other events requiring an integrated laboratory response

Building Environmental Laboratory Capability in Support of Emergency Response

level

RFAs have been identified at Dept

Identified agency responsible for ensuring capability exists, though actual capability may exist in another Dept

Filling a cell on this chart does NOT mean the capability really needs to exist under current prevailing threat conditions

> MOAs/MOUs will be required to clarify supporting agency roles and commitments to RFAs

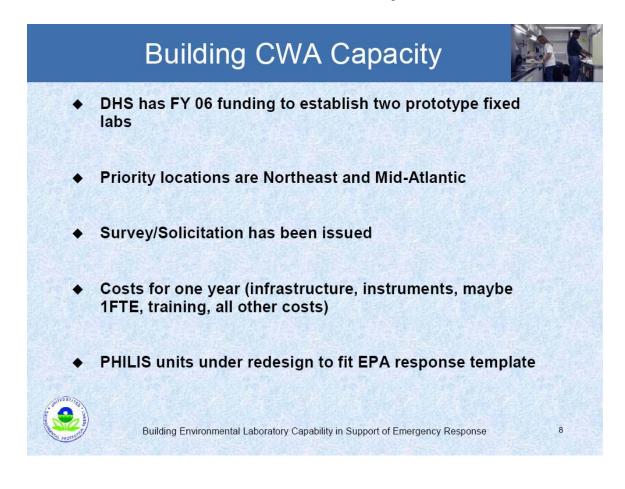

6

Status

- NCG has met monthly since March of 2005 -Formed operational relationships and assignments -Established 6 Technical Expert Panels -Identified gaps in capacity and budgetary needs -On-going review of 9 Scenarios to test lab capacity
- JLC met September 2005
 - -Affirmed RFA assignments
 - -Supported unified approach to address CWA and Rad gaps -Supported unified budget proposals for all network needs

Priorities for CWA and Analytical Enhancements for eLRN

9

♦ Form and operate an environmental laboratory response network and build increased CWA capabilities/capacities for environmental samples

Enhance Lab Analytical Capabilities

-Develop additional CWA environmental state laboratory capabilities through grants/cooperative agreements

OR

-Purchase and operate PHILIS – portable high-throughput mobile unit(s)

Align eLRN with other networks through proficiency testing, data management, and other analytical resources

Building Environmental Laboratory Capability in Support of Emergency Response

EPA's Environmental Laboratory Response Program

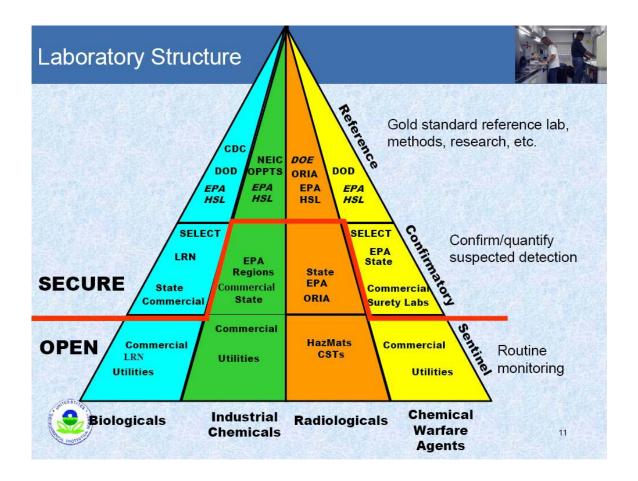

The Environmental Laboratory Response Program

- Virtual Center/Program Office now operational
- Focus of 06 to model Toxic Industrial Chemical (TIC) network as template
- Engaged Federal and State Partners and will need continued interaction
- Engaged APHL to provide State access
- Evaluated HSPD 10 Scenarios
- BOAs/IAG in place to partially address CWA needs
- Resolved Ultra-dilute CWA program w/ DOD
- All Hazard Receipt Facility prototypes Summer 2006*
- WaterSentinel proceeding on own track
- PHILIS Units role redefined and retrofit/redesign proposed

22nd Annual National Environmental Monitoring Conference

Homeland Security Laboratory Response Program

Roles and Responsibilities defined and agreed upon

- Participate in ICLN/NGC/POE activities
- Need to establish formal relationships with external member laboratories
- Need to formalize internal EPA laboratory roles and responsibilities

Understand capabilities

- Continue to fine tune a <u>complete</u> inventory of Federal, State and private laboratory capability
- Address gaps and identify appropriate investments needed
- Carry out a national review of chemical, biological and radiological capability
- Previous EPA/State/limited private laboratory Compendium undergoing web update

Focus on needed methods

- Develop core set of HS methods at EPA
- Collaborate with DOD/Other entities
- Provide appropriate technical assistance

<section-header><section-header><section-header><list-item><list-item><list-item><list-item><list-item>

HSLRWG

- Standardized Analytical Methods for Use During Homeland Security <u>Events</u> (SAM)
 - List of methods for use in identifying chemical and biological agents that could be used as weapons of mass destruction.
 - Version I published and distributed in September 2004.
 - Version II is now complete and has undergone SAB review (www.epa.gov.nhsrc)
- Recent ORD activities:
 - National Homeland Security Research Center (NHSRC) currently determining prioritization of FY 06 methods development & validation
 - NEMC-Las Vegas will serve as Agency chemical reference lab

Building Environmental Laboratory Capability in Support of Emergency Response

17

Other Activities

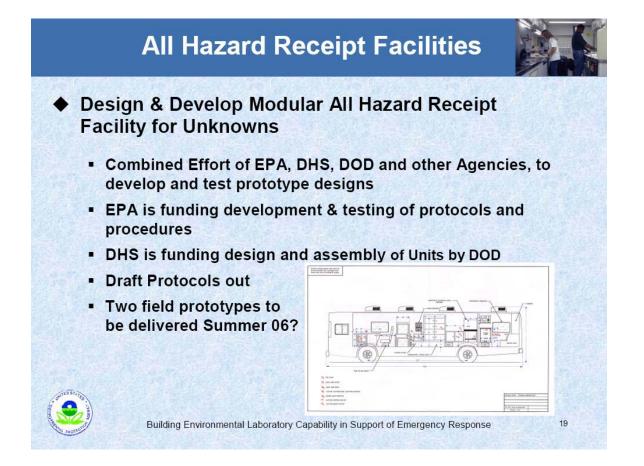

18

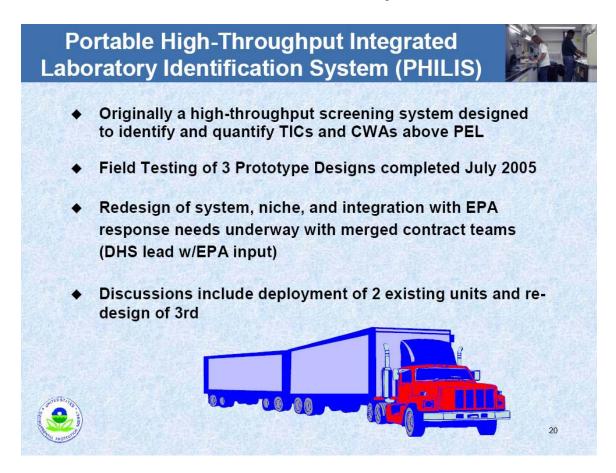

- EPA's Lab Response Compendium (www.epa.gov/compendium)
 - EPA's Compendium is a web-based system designed to identify laboratory capabilities to analyze full range of chemical, radiochemical, and biological analytes
 - Data has been received from over 280 State, Commercial, and EPA laboratories (need data from non-EPA Federal Labs)

HSPD 10 Tasking

- 5 of the Whitehouse Homeland Security Council threat scenarios reviewed to determine the number of analyses required for large scale releases
- Current capacity was estimated using the EPA Compendium, CDC and its LRN laboratories, US Army Medical Information Research Institute of Infectious Diseases, and DOE

Next Steps

External

- Develop national strategy with DHS to address gaps in environmental analyses
- Expand the national capacity for Chemical, Biological and Radiological analysis in environmental samples
- Participate with ICLN Networks
- Outreach to States, other stakeholders

Internal

- Continue formation of eLRP
- Continue work on WaterSentinel
- Develop and deploy All Hazard Receipt Facilities
- Develop 08 Budget approaches
- Continue HSRC/NEMC activities

21

ENVIRONMENTAL LABORATORY RESPONSE NETWORK

Rothman, R.; USEPA

Following the 9/11/2001 attack and the subsequent anthrax events, it became apparent that EPA would have to be better prepared to respond to the possibility of future chemical, biological and radiological attacks. One key area of concern is laboratory capability/capacity. Historically, EPA has focused on toxic industrial chemicals. New high risk threats such as chemical warfare agents (cwas), toxins, biological agents and radionuclides visa vi "dirty booms", all pose catastrophic risk that would require a massive timely laboratory response.

When responding to an event, lab results would need to be of high quality, fast and consistent. To accomplish this, EPA must first establish reliable and validated analytical methods for each agent on concern. For many of these agents, proven methods simply do not exist and are complicated by various environmental media/conditions. At the same time methods are being developed, laboratory capacity is needed to receive potentially 10s of thousands of samples per week. This kind of capacity for the more than 100 high risk threat agents is daunting, particularly given the cost for method development, specialized equipment, training requirements and the need for regional representation.

This presentation will discuss some of the National Homeland Security Research Center's (NHSRC) initiatives to support laboratory capacity and capabilities. This includes the latest publication of the Standard Analytical Methods (SAM) that highlights agents of concerns and preferred analytical methods. In many cases, indicated methods are considered "best fit" but are not validated. Other initiatives addressed in this presentation include cwa and biological method development, expansion of lab capacity through the DHS philis, and establishment of the network reference lab in Las Vegas Nevada.

- Support ELRN--CWA

Sampling and Analytical Planning For Re-Entry and Recovery Following a Chemical Release Incident – Thinking Ahead

Hewett, Paul L.; Kimmell, Todd A. Argonne National Laboratory

Chemical warfare agents have been released in a major metropolitan area. The initial response, which included evacuation of a portion of the population, has been completed and several days have elapsed. Pressure for allowing the evacuated public to return to their homes is mounting, but decision makers want a high degree of certainty that risks are acceptable before return is allowed. Sampling and analysis of various media are needed over a wide area as input to the determination of acceptable risk. A high degree of certainty translates to hundreds, perhaps thousands of samples.

- How can we be prepared with all the resources needed to support the sampling effort, including sample handling and transport?
- Given laboratory capacity limitations, how can we make sure that we are not taking more samples than our laboratories can handle?
- Given the number of samples and laboratories and the need for some level of data quality review, when will data be available to support decision making?
- What effect would bringing on additional sampling teams or laboratories have?
- How much will the sampling and analytical effort cost?

While decision makers may agree on the number of samples to support an agreed-upon level of certainty, they must be aware of the level of resources and amount of time it will take to obtain results. The purpose of this presentation is to review concepts for thinking ahead in determining the magnitude of the sampling and analytical effort required to support re-entry and recovery following a chemical release incident.

Sampling and Analytical Planning for Re-Entry Following a Chemical Release Incident: Thinking Ahead

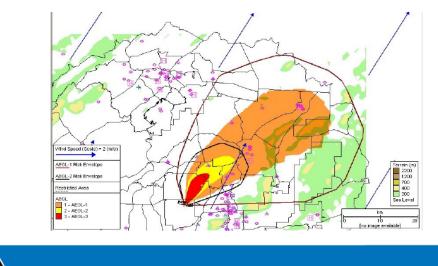

22nd Annual National Environmental Monitoring Conference

Todd A. Kimmell and Paul L. Hewett, Jr.

Hypothetical Scenario

- Chemical warfare agents released in a major urban area
- Vapor cloud forming a plume with subsequent deposition
- Population evacuation

Hypothetical Scenario

- Several days have elapsed and Subject Matter Experts are suggesting that agent has degraded or dispersed to acceptable levels
- Pressure is mounting for allowing population re-entry
- Decision makers want a high degree of certainty that risks are acceptable before return is allowed
- Sampling and analysis of various media are needed over a wide area to support a risk determination

We recently attended an emergency response exercise that had a similar scenario. Without considering resources and timing, decision-makers selected a certainty of 95% for data in support of a re-entry decision.

Major Considerations for Re-Entry

- Meeting a high level of certainty can translate to a need for thousands of samples and multiple analyses per sample
- Many issues will require a quick but well-reasoned resolution
- The logistics of the sampling and analytical operation can be very complex
- The resources needed to support the operation can be extensive and a constant supply of consumables is needed
- The sampling and analytical effort can take many days to complete

During the exercise, to meet 95% certainty, a sampling and analytical plan was developed that called for approximately 3,000 samples. When asked about sample through-put, the response was: We have two laboratories that can each process 500 samples per day – 3 days.

But Let's Get Real

- How many sampling teams, and of what makeup, would it take to collect 500 samples per day (not including QC samples), considering:
 - Travel from sampling site to sampling site (some indoors)
 - Sample documentation
 - Safety concerns and personal protective equipment (PPE)
 - Sample screening and decontamination
- How many laboratories, running two or three methods per sample, would it take to process 500 samples per day, considering:
 - Laboratory documentation
 - QA/QC and procedures
 - Common laboratory issues

You can throw more sampling teams and laboratories at the problem, but what affect will this have on the logistics, resources and timing?

And What of Other Issues?

- Many issues may be faced in developing a sampling and analytical plan in support of emergency response and re-entry
 - Overarching Programmatic Issues
 - Logistical Issues
 - Technical Issues
- Many of these issues have tremendous implications in terms of public acceptability, resources considerations, timing, and liability
- Should decision-makers be involved in resolution of these issues?

Absolutely. But were decision-makers involved in issue resolution during the exercise? Were these issues even addressed during the exercise? Is it wise to address these issues during a real emergency response?

Lets take a quick look at some of the issues...

Programmatic "Overarching" Issues

- Technical approach to sampling (Statistical vs. Judgmental, Direction relative to Plume)
- Level of Certainty or Degree of Confidence
 - How sure do you want to be that you have not missed a hot spot?
 - How sure do you want to be that you have not misidentified a chemical?
- Decision Criteria
 - What levels (concentrations) are acceptable (safe)?
 - Will these levels be acceptable to the public?
 - Will any level be acceptable to the public?
 - What about degradation products?
- The Decision-Making Process
 - Who decides? On what basis? When? Is it a phased re-entry?
 - Adoption of National Incident Management System (NIMS) Incident Command System (ICS) – Incident Command Structure

Logistical Issues

- Timing and Coordination
 - Sampling and analysis (sample collection, screening, packaging, security, transport, analysis)
 - After analysis (reporting, quality reviews, databasing, evaluation, presentation, decision making)
- Accessibility of sampling locations
 - Grid points may translate to inaccessible locations
 - Private property issues and need for escort
- Resources
 - Consumables and non-consumables
 - Purchasing agreements
- PPE and decontamination requirements
- The weather!

Technical Issues

- Site Conceptual Model (SCM) and Data Quality
 - Even though its an emergency response you still need a SCM!
 - Pre-definition of desired level of data quality
- Analytical Methods
 - Laboratory Methods (Traditional Approach)
 - Field Methods (EPA's Triad Approach)
- Positive Results
 - False positives (or negatives)
 - Decision process
- Data Quality Evaluation
 - Screening assessment
 - Verification or Validation?
- Data Management (database selection and management of multiple formats)

So, How Can We Get Prepared?

- Site- or situation-specific policy and guidance PREPARED BEFOREHAND
 - Resolves or at least explores the issues in different scenarios
 - Agreed to by decision-makers likely to be included in an incident command structure, perhaps with public input
- Training and emergency response exercises
 - Specific to the re-entry phase
 - Modeled on the National Incident Management System (NIMS) and Incident Command System (ICS)

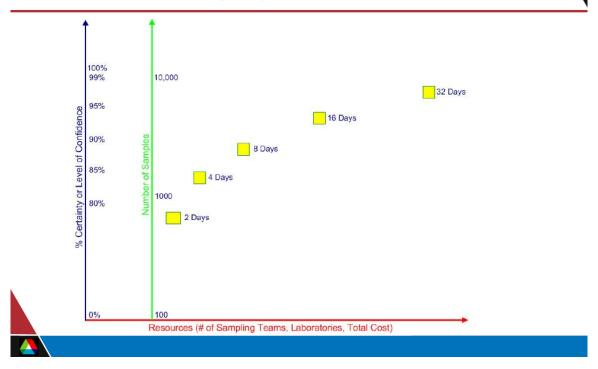

Pre-Evaluation of Decision Criteria

Decision-makers need to be able to select a level of certainty or a level of confidence WHILE UNDERSTANDING the number and types of samples that need to be collected, the types of analyses that need to be performed, the issues and their implications, the amount of resources needed (personnel, equipment, consumables, funding), and the time that will be needed to complete sampling and analysis and related activities, and come to an informed decision.

Consider the following diagram...

Argonne's Synchronization Matrix (Sync Matrix[©]) Software

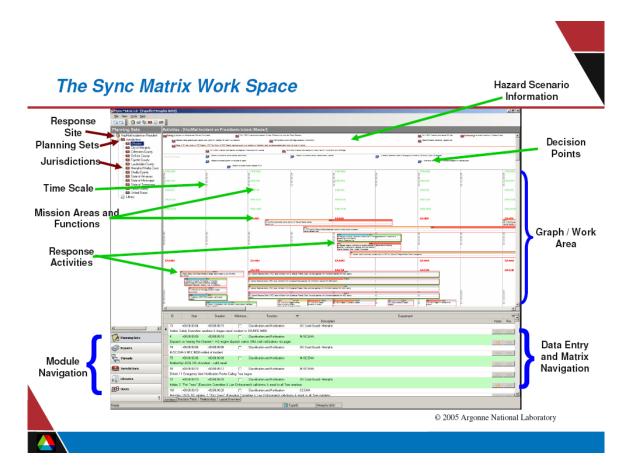

- What is Sync Matrix?
 - A planning software package intended to facilitate development, integration, coordination and synchronization of emergency response planning
 - A graphic depiction of a community's intended response, synchronized across time, space, and purpose in relation to a specific hazard scenario
 - Scenarios are limitless (hurricane, tornado, train derailment, chemical release, improvised explosive device, evacuation, event planning)

A "Sync Matrix" plan provides the framework from which you adapt a response, not a script to be followed to the letter.

Sync Matrix Planning

- Views emergency response as a set of human activity systems
- Uses a problem solving approach to planning
- Emphasizes relationships between the actions and capabilities of the various jurisdictions and departments within jurisdictions involved in a response
- Organizes activities over time by mission areas and functions, which are groupings of related response activities (e.g., monitoring and sampling)
- Identifies activities and relationships between activities over time in relation to the hazard scenario (e.g., hurricane landfall) and decision points (e.g., disaster declaration)

So we developed a Sync Matrix to plan-out sampling and analysis activities for re-entry, based on the exercise. Lets take a look, but first a quick primer on Sync.

By developing a Sync Matrix for the Exercise SAP we were able to show...

- The complexity of the sampling and analytical operations and support functions
- The time involved for the various steps of the process, by function and by jurisdiction
- The relationships between each of the jurisdictions
- The overall time required for each sampling/analysis phase
- The overall time for the entire operation

Using two sampling shifts per day, with two teams per shift, one on-site laboratory (for hot samples), one laboratory within driving distance, and three off-site laboratories, and considering data management and reporting, it was almost 12 days before an informed decision, based on 95% certainty, could be made.

ETV and Real World Deployment Testing of an On-line, Learning Based System for Drinking Water Security Monitoring

Dan Kroll, Karl King and Greg Klein

Hach Homeland Security Technologies, Loveland, Colorado

ABSTRACT

The drinking water distribution system is vulnerable to deliberate or accidental back flow events. The large number of agents that could be potential threats and the innumerable access points make this a difficult scenario to defend against. This was clearly stated in a GAO report to Congress that listed the vulnerability of the distribution system to attack as the largest security risk to water supplies. A system designed to address the problem of distribution system monitoring is described here. The developed system employs an array of common analytical instrumentation, such as pH and chlorine monitors, coupled with advanced interpretive algorithms housed in an event monitor to provide detection/identification-response networks that are capable of enhancing system security. A variety testing protocols were used to verify the efficacy of the system. Data obtained from a Battelle/EPA ETV study and a cooperative research and development agreement (CRADA) between Hach HST the EPA Office of Research and Development addresses issues such as long-term deployment and ability to detect and characterize contaminants. Information obtained from test loop studies carried out by Hach HST, the US Army Corp of Engineers Research Lab, and the Edgewood Biological and Chemical Command as the result of a 3-way CRADA demonstrate data collected when the system is exposed to actual warfare agents. Real world deployment data is used to demonstrate recognition and classification of actual events. The system is shown to be a practical measure to help detect and characterize backflow events.

INTRODUCTION

The recognition that our water supplies are vulnerable to sabotage is not a recent discovery made after the attacks of 9/11. As early as 1941, just after the surprise attack on Pearl Harbor, FBI Director J. Edgar Hoover wrote, "Among public utilities, water supply facilities offer a particularly vulnerable point of attack to the foreign agent, due to the strategic position they occupy in keeping the wheels of industry turning and in preserving the health and morale of the American populace. Obviously, it is essential that our water supplies be afforded the utmost protection."¹ The US Military also recognized the threat prior to 9/11. The historic department of defense policy that requires domestic military base reliance on local utility infrastructure whenever possible was explored and recognized as a threat by Major D. C. Hickman in his seminal report issued in September of 1999 entitled "A Chemical and Biological Warfare Threat; USAF Water Systems at Risk.² There is a long history of water being vulnerable to such attacks.

That the water supplies are a target is also reinforced by the fact that domestic terrorist and fringe groups have shown continued interest in using a Chemical, Biological, or Radiological (CBR) agent in their attacks and Islamic terrorist groups have also exhibited interest in water supply

systems. While these attempts were thwarted, as history shows, al Qaeda has a unique ability to diligently perfect and refine attack strategies. This threat is particularly important for U.S. military bases, as it is for private and government "icon" facilities. Researchers from the U.S. Air Force and Hach Homeland Security Technologies (HST) have calculated that an attack on drinking water distribution systems can be mounted for between \$0.05 and \$5.00 per death, using rudimentary techniques, and amass casualties in the thousands over a period of hours.^{3,4}

While the threat from Islamic terrorists is dire, it is not the only threat. Domestic terrorists and disgruntled employees may represent a scenario just as serious and possibly more likely. Even though threat of deliberate attack gets a lot of attention, the greatest vulnerability to water quality in the distribution system is not from intentional contamination but accidental contamination due to mistakes made in systems operation or failure of aging infrastructure. Many components of the ageing U.S. drinking water distribution system are verging on collapse. These failures in the system can be of a catastrophic nature, such as a burst pipe, or, as is more often the case, the slow degradation of the system that can lead to infiltration of contaminants from ground water or other sources. Do to the meager monitoring that is currently being done in the distribution system many of these types of problems remain undetectable until they result in a catastrophic failure or a disease outbreak.

When observing a typical municipal water supply system (Figure 1) it is natural to assume that the main point of vulnerability to a CBR attack would be the introduction of an agent into the system at the source water (reservoir) or treatment plant. However; in order to create widespread casualties from an attack on the source water, the amount of contaminant required would, after taking dilution into account, be either too large to handle easily or be more expensive than other readily available terrorist weapons. Within the water industry, this concept is summarized by the phrase *dilution is the solution to pollution*. Blind acceptance and reliance upon this strategy for protecting water has delayed the recognition of the true danger, as it exists, little own the timely adoption of possible ways to mitigate the problem. It is only gradually that the industry has come to recognize that the dilution of pollutants is not a viable means to deal with the vulnerability, as not all components of the system would dilute a toxin to non-hazardous levels.

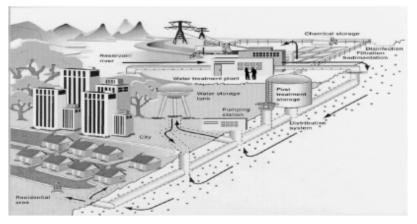

Figure 1: A Representative Municipal Water Supply System

Initially after the attacks of 9/11, government experts declared that, due to this dilution factor, our water supply systems were fairly secure. Ronald Dick, FBI Deputy Assistant Director for

Counter Terrorism Division, stated in testimony before congress that "In reality, targeting the water supply may prove difficult. In order to be successful, a terrorist would have to have large amounts of agent."⁵ EPA administrator Christie Whitman stated on 10/18/2001, "People are worried that a small amount of some chemical or biological agent – a few drops for instance – could result in significant threats to the health of large numbers of people. I want to assure people – that scenario can't happen. It would take large amounts to threaten the safety of a city water system. We believe it would be very difficult for anyone to introduce the quantities needed to contaminate an entire system."⁶

The concept of dilution providing security for the system was short lived. It wasn't long before government officials and industry experts realized that the crucial vulnerability to contamination was is the distribution system. By October 2003, a GAO report to the Senate stated that the distribution system was the area most vulnerable to attack.⁷ Conceding that an attack with CBR agents would most likely take place somewhere in the distribution system, several misconceptions about this type of attack still persist. Historic (and incorrect) dogma holds that such attacks require the assistance of several technicians, are expensive to carry out, and require complicated and expensive pumping equipment to inject contaminants into a pressurized system. More recent studies by the Army Corps of Engineers and Hach HST, among others, show that CBR attacks could in fact be carried out for 5 cents or less per lethal dose, that a single individual can obtain or produce effective contaminants in quantity, and that contaminants can be introduced into the distribution system with the aid of inexpensive and easy to obtain pumping equipment via a method called backflow attack.⁸

A backflow attack occurs when a pump is used to overcome the pressure gradient that is present in the distribution system's pipes. This is usually around 80 lbs/in² and can be easily achieved by using pumps available for rent or purchase at most home improvement stores. After the pressure has been overcome and a contaminant introduced, Bernoulli effects pull the contaminant into the flowing system and the normal movement of water in the system acts to disseminate the contaminant throughout the network effecting areas surrounding the introduction point. The introduction point can be anywhere in the system such as a fire hydrant, commercial building or residence. See Figure 2. Studies conducted by the US Air Force and Colorado State University have shown this to be a very effective means of contaminating a system.⁸ A few gallons of highly toxic material was enough, if injected at a strategic location via continuous feed, to contaminate an entire system supplying a population of 150,000 people in a matter of a few hours. A terrorist could launch such an attack and be on a plane out of the country before the first casualties begin to show up.

Figure 2: All distribution systems are vulnerable to a backflow attack. The attack point can be anywhere in the system.

Currently, monitoring of drinking water supplies in the distribution system is limited. Previous to the terrorist threat, it was not a priority. The ability to detect an event in the distribution system and then identify it would be of incomparable value in responding to an incident in a timely and proper manner. Such an ability would also serve the purpose of mapping a system for clean up, and after words, it could be used as a forensic tool to identify the source of an event. Prior to this, there has not been a device capable of detecting such an event and alerting the system's managers so that the effects of an attack or accidental event can be contained. The general scientific consensus is that no practical, available, or cost-effective real-time technology exists to detect and mitigate intentional attacks or accidental incursions in drinking water distribution systems. The development of such a monitoring system was listed as by a panel of experts and industry leaders as a top priority in enhancing water security.⁹

Security monitoring in the distribution system is a difficult proposition. The shear number and diversity of potential threat agents that could be utilized in an attack against the system makes monitoring for them on an individual basis an effort that is doomed to failure from the start. What is needed is a broad-spectrum analyzer that can respond to any possible threat and even unknown or unanticipated events.

This need to detect such a large number of diverse contaminants requires a realignment of thinking from the traditional development of a sensor for a given compound or agent. Sensor arrays on a chip or the use of analytical instrumentation capable of detecting this variety is a definite challenge. Another approach is to use chemometrics to detect and characterize changes in basic water quality parameters and correlates them with threat agent introduction. This is the approach chosen by Hach HST and detailed in the remainder of this paper.

THE HACH HST APPROACH

Rather than attempting to develop individual sensors to detect contaminants or classes of contaminants, the Hach HST approach is to utilize a sensor suite of commonly available off-the-shelf water quality monitors such as pH, electrolytic conductivity, turbidity, chlorine residual and total organic carbon (TOC) linked together in an intelligent network. The logic behind this is that these are tried and true technologies that have been extensively deployed in the water supply industry for a number of years and have proven to be stable in such situations. One of the difficulties encountered when designing such a device is that the normal fluctuations in these parameters found within the water can be quite pronounced.

The problem then becomes, can we differentiate between the changes that are seen as a result of the introduction of a contaminant and those that are a result of everyday system perturbation? The secret to success, in a situation such as this, is to have a robust and workable baseline estimator. Extracting the deviation signals in the presence of noise is absolutely necessary for good sensitivity. Several methods of baseline estimation were investigated. Finally, a proprietary, patented, non-classical method was derived and found to be effective.

In the system as it is designed, signals from 5 separate orthogonal measurements of water quality (pH, Conductivity, Turbidity, Chlorine Residual, TOC) are processed from a 5-paramater measure into a single scalar trigger signal in an event monitor computer system that contains the algorithms. The signal then goes through the crucial proprietary baseline estimator. A deviation of the signal from the established baseline is then derived. Then a gain matrix is applied that weights the various parameters based on experimental data for a wide variety of possible threat agents. The magnitude of the deviation signal is then compared to a preset threshold level. If the signal exceeds the threshold, the trigger is activated.

The deviation vector that is derived from the trigger algorithm is then used for further classification of the cause of the trigger. The direction of the deviation vector relates to the agents characteristics. Seeing that this is the case, laboratory agent data can be used to build a threat agent library of deviation vectors. A deviation vector from the monitor can be compared to agent vectors in the threat agent library to see if there is a match within a tolerance. This system can be used to classify what caused the trigger event. This system can also be very useful in developing a heuristic system for classifying normal operational events that may be significant enough in magnitude to activate the trigger. When such an event occurs the profile for the vector causing it is stored in a plant library that is named and categorized by the system operator. When the event trigger is set off the library search begins.

The agent library is given priority and is searched first. If a match is made, the agent is classified. If no match is found, the plant library is then searched and, the event is identified if it matches one of the vectors in the plant library. If no match is found, the event is classified as an unknown and can be named if an investigation determines its cause. This is very significant because no profile for a given event need be present in the libraries for the system to trigger. This gives the system the unique ability to trigger on unknown threats. Also, the existence of the plant library with its heuristic ability to learn plant events results in a substantial and rapid decrease in unknown alarms over time. The developed system has been subjected to strenuous testing in both

laboratory and field scenarios as detailed in the remainder of this paper and has been found to be an effective tool for surveillance of the distribution system.

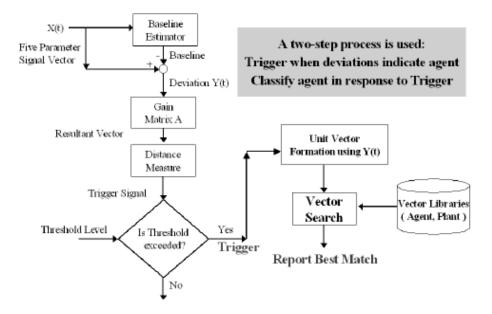

Figure 3: The use of intelligent algorithms with standard bulk parameter monitoring equipment allows for a robust system that is capable of triggering on and classifying a wide diversity of threat agents including.

BATTELLE EPA ETV VERIFICATION TESTING

In the fall of 2004, the developed technology was submitted for testing to the EPA Environmental Technology Verification (ETV) testing program run by Battelle. The ETV Program develops testing protocols and verifies the performance of innovative technologies that have the potential to improve protection of human health and the environment. ETV was created to accelerate the entrance of new environmental technologies into the domestic and international marketplace. The category being tested was Multi-parameter Water Monitors for Distribution. The technologies verified needed to function on line and be capable of monitoring chlorine and at least one other parameter. The tested technologies were evaluated for accuracy of instrument readings versus reference methods, ability to maintain integrity during long term deployment, system to system variability, ability to respond to contaminants, and classification of unknown contaminants (The Hach system was the only one evaluated for ability to classify contaminants). The complete ETV report and an explanation of the report can be down loaded at: [http://www.hach.com/fmmimghach?/CODE:ETV EMTS-WDMP9266]1//true] and [http://www.hach.com/fmmimghach?/CODE:ETVEXP-HACHHST9203]1//true].

Accuracy

The on-line instruments were evaluated on an individual basis versus standard laboratory methods for the given parameters. See Table 2.

Evaluation	ı Parameter	Cl	Turb	Con	pН	TOC
				d.	P	
Stage 1	Units 1 &	-47.4 to	-53.9	-15.5	-6.6	-64.7 to
Accuracy	2, range of	4.5	to –	to	to 3.1	147.5 (-
	%D	(-3.9)	1.3	8.1	(0.9)	14.8)
	(median)		(-	(2.2)		
			34.1)			

Table 2: Accuracy

Overall accuracy of all of the parameters measured was very good and correlation to laboratory methods was strong. Small absolute values in turbidity and TOC lead to large %D. Due to sampling errors in some cases on-line instrument readings may be more reliable than the reference method e.g. chlorine.

Inter-Unit Reproducibility

Two separate but identical sets of instrumentation were deployed for the duration of the study. Measurements versus reference instruments were compared through out the course of the study.

Table 5. Reproductointy										
Para	neter	Cl	Turb.	Cond.	pН	TOC				
Inter-unit	Slope (intercept)	0.98	0.97	0.92	1.06	0.97				
Reproducibility		(0.03)	(0.005)	(4.19)	(-0.40)	(0.31)				
	r ²	0.994	0.881	0.961	0.919	0.991				
	p-value	0.779	0.884	0.006	0.517	0.374				

Table 3: Reproducibility

With the exception of conductivity both units generated similar results. See Table 3.

Contaminant Injection

During this phase of the test the instruments were installed in a recirculating pipe loop. Various contaminants were injected to determine if they altered the baseline response pattern of the instruments. Similar injections were preformed after the long-term deployment test to ascertain if there had been any degradation of instrument response.

Total chlorine and TOC were dramatically affected by injections of nicotine, *E. coli*, and Aldicarb; and turbidity, pH, and conductivity were affected by some or all of the injections, but not as consistently as total chlorine and TOC. Aldicarb altered pH during testing after extended deployment but not before. See Table 4. Agreement in both cases with reference readings indicates that the instruments were functioning properly and, the difference was in the injection preparation.

-							
Paramete	r		Cl	Turb	Cond	pН	TOC
Initial response	Nicotine	Ref	-	(a)	NC	NC	+
to injected contaminants		Hach	-	+	NC	NC	+
	Arsenic	Ref	-	(a)	+	+	NC
	Trioxide	Hach	-	+	+	+	NC

		Hach	-	+	NC	NC	+
Response after extended	E. coli	Ref	-	+ ^(b)	+	-	+
deployment		Hach	-	+	+	-	+
	Aldicarb	Ref	-	+ ^(b)	NC	-	+
		Hach	-	+	NC	-	+

Table 4: Response to Contaminant Injection

(a)Relatively large uncertainty in the reference measurements mad it difficult to detect a significant change; (b)Magnitude of change different between duplicate injections; +/-Parameter measurement increased/decreased upon injection; NC No change in response to contaminant injection

Long-term Deployment

During this phase of the testing, the systems were operated continuously for 52 days with only normal maintenance, such as reagent replenishment, being performed. During the course of the test, instruments were regularly compared to reference instruments. See Table 5. At the end of the 52 days a second response to contaminant injection procedure was performed. See Table 4. The results of the extended deployment study indicate that the system can be effectively deployed for long periods of time with only routine maintenance. Relative large %D in turbidity and TOC measurements are artifacts of the low total values for these parameters encountered during the testing procedure and do not indicate a problem with these sensors.

		Unit I	l	Unit 2	
Parameter	Reference Average (SD)	Average (SD)	%D	Average (SD)	%D
Free chlorine	1.03 (0.03)	0.98 (0.02)	-4.9	0.98 (0.02)	-4.9
Turbidity	0.17 (0.02)	0.16 (0.03)	-5.9	0.15 (0.04)	-11.8
Temperature	22.66 (0.16)	22.61 (0.03)	-0.2	23.70 (0.06)	4.6
Conductivity	356 (1)	380 (1)	6.7	357 (1)	0.3
րН	8.59 (0.01)	8.40 (0.01)	-2.2	8.61 (0.00)	0.2
TOC	0.88 (0.01)	0.70 (0.01)	-20.5	0.91 (0.01)	3.4

Table 5: Post-extended Deployment Results

Inter-Unit Reproduceablity

Two Hach units were compared, using data collected from reference samples throughout the verification test to determine whether similar results were generated. See table 6.

For free chlorine, pH, TOC, and turbidity, the linear regression had coefficients of determination greater than 0.91 and slopes within 6% of unity, indicating similar and repeatable results. The t-

test p-values confirmed the sensors were generating statistically similar results. The conductivity meters had a linear regression coefficient of determination of 0.961 and a slope of 0.92, indicating that the data were highly correlated with one another. The t-test generated p-values significantly less than 0.05, which indicated that the results from the two conductivity sensors were significantly different. This difference was driven by the small amount of variability in the conductivity measurements; therefore, the small difference between the means of the two units was statistically significant. It is important to note that the offsets in the measured parameters do not affect the performance of the algorithm because the baseline is removed and the classification is performed based only on deviations from baseline.

-		-	2	
Parameter	Slope	Intercept	r	t-test
				p-value
Free chlorine	0.98	0.03	0.994	0.779
Turbidity (outlier removed)	0.97	0.005	0.881	0.884
Temperature	0.72	7.68	0.758	5.5 × 10-0
Conductivity	0.92	4.19	0.961	0.006
pH	1.06	-0.40	0.919	0.517
TOC	0.97	0.31	0.991	0.374

Table 6: Inter-unit Reproducibility Evaluation

Shading indicates a significant difference between the two units.

Contaminant Classification

During the final stage of the verification test thirteen contaminants (See Table 7) were injected at a concentration of approximately 15 mg/L, in duplicate, into a 1500 foot straight line pipe and allowed to flow past the monitoring sensors. Every contaminant injection resulted in the system exceeding the trigger threshold and producing a corresponding agent alarm. Each minute-byminute search of the agent library can result in more than one agent being identified. For both Hach Units, the agent alarms occurred as few as eight times and as many as 79 times during the 20-minute injection periods. No agent alarms occurred outside of the 20-minute injection periods. If the system recognized deviations from the baseline, the agent library identified and recorded these deviations as "unknown" event. Due to the dynamic nature of the leading and trailing edges of the injected contaminant, it is possible that an injection event generated alarms other than the known injected contaminant. Table 7 shows all contaminant injections classified according to the fraction of agent alarms attributable to the correctly classified injected contaminant. The data is depicted concisely by classification rates divided into five levels: Level 5 - greater than 70%, Level 4 - between 31% and 69%, Level 3 - between 1% and 30%, Level 2 - injected contaminant not identified but other contaminants were identified, and Level 1 no injections detected.

From the tests conducted on Hach Version 1 System, weak results were obtained for Methanol and Dichlorvos, while poor results were obtained for Glyphosate, Nicotine, Arsenic Trioxide and *E. coli*. The data from the tests on VERSION 1 of the HHST technology at the EPA center were recorded at the time of the tests. The Event Monitor Trigger System also acts as a data logger and provides a copy of the sensor signals recorded during the tests. This situation afforded us the ability to analyze failures detected in the VERSION 1 tests, improve and upgrade software, and then replay new versions of the technology to test for efficacy. A variety of causes were found to affect the test results of VERSION 1.

Because of a misunderstanding, the original Version 1 threat agent library included Round-UP Herbicide (a form of glyphosate), while the ETV protocol used pure glyphosate. When pure Glyphosate was added to the agent library in Version 3, the system correctly classified the agent.

HHST had previously tested nicotine (in house, and at ECBC) with good results. However, the data from the ETV test facility revealed that the excessive mixing method employed prior to injection had caused the nicotine base to react with the carbon dioxide in the air, changing the chemical nature of the contaminant. The Agent Library was improved by adding a signature for reacted nicotine, and Version 3 shows the positive test results. These two examples demonstrate the sensitivity of the system, and how the comprehensive data structure of its Agent Library derives its classification accuracy.

In addition while first developing the Agent Library, HHST employed bench-scale chlorine analyzers that contained EDTA (a metal sequestering agent) as a reagent component, whereas the EMTS sensor panel includes chlorine analyzers that do not use this substance. The EPA/ETV tests revealed this flaw, and VERSION 3 includes upgraded library signatures. Signatures for some other agents were examined for tabular errors and those were corrected as needed. This second set of test results could not be included in the ETV report, as any re-testing was not a part of the original test protocols. Following analysis and upgrades, two succeeding algorithm versions were produced; the test results from VERSION 3 is summarized in Table 8.

~

BEAKER TESTING AND FLOW LOOP TESTING AT EDGEWOOD CHEMICAL AND BIOLOGICAL COMAND (ECBC)

The purpose of this effort was to challenge water distribution systems and sensors, with agent simulants and real threat agents, in order to characterize the response of the distribution system and Early Warning System to agents. Agent concentrations and water solutions were varied to allow for the development and demonstration of distribution methodologies and performance data acquisition. In addition, this work evaluates the effectiveness of Hach Homeland Security Technologies real-time detection technology and provides important information necessary for the U.S. Army to perfect its theories of operation and response mechanisms. The scope of the work performed during these tests was two fold. The first part of the test was to perform beaker studies on agents that are not available for use in the Hach Laboratories in Colorado such as VX, Sarin, Soman, Ricin and Anthrax etc. The second part of the testing protocol called for verification of signatures in a flowing loop to validate the transfer of the beaker signature data to real world scenarios. See Figure 4.

It is known that in a real attack on a water distribution system the concentrations of the agents would vary throughout the distribution system. The concentrations tested were to either infectious amounts, ID₅₀, for replicating agents, or LD₅₀ amounts for chemical agents. Each agent was tested at three dose values, as defined in a test plan matrix. Two types of disinfectant are commonly used in water distribution systems: free chlorine, and monochloramine. It is necessary to test agents in both types of media to have information representative of each type. It is also clear that variable amounts of chlorine would be in the distribution system water, so tests used different solutions: 0.2 ppm Free Available Chlorine (FAC), 1 ppm FAC, and 2 ppm Monochloramine, as these are the limits of typical system concentration. Monochloramine is usually less variable in concentration and can be tested at typical values. Real-time loop tests were run on nicotine, ricin, BA, and methanol.

Figure 4: Hach HST constructed a special variable volume flow loop inside of an ECBC surety chamber.

All fingerprints were successfully developed and ROC curves were generated for all agents tested. It was also found that the fingerprints developed from the lab work could be successfully transferred to a flowing system by successfully triggering and classifying agents in the flow loops. Because of security concerns and confidentiality, only selected nicotine test data is provided in Figures 5 and 6.

The test concentration of nicotine was 19.7 mg/L. In a single test run, nicotine was recognized by the system, with detection angles ranging from 0.94 degrees (essentially a perfect match) to 9.84 degrees (a weak match). The fluctuating trigger signal is due to the mixing dynamics of a recirculating loop.

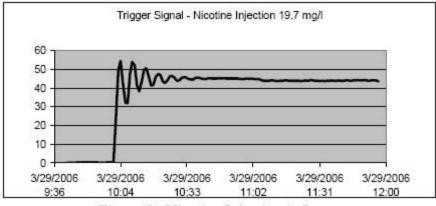

Figure 5: Nicotine Injection in Loop

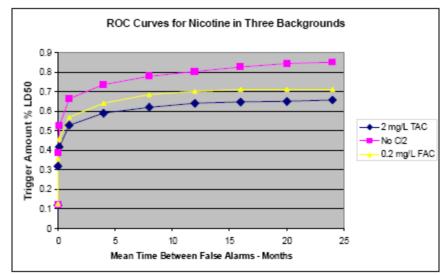

Figure 6: ROC Curves for Nicotine in Three Backgrounds

Threshold trigger levels range from 0.36 to 1.26 for all curves

FIELD TESTING OF THE DEVELOPED SYSTEM

Figure 7: A Real World Deployment Site Showing the System in Operation

Prior to the onset of this project, there was a definite lack of data concerning conditions in the distribution system. Very few utilities carried out data collection in the distribution system othe than periodic grab samples. Those that did have some on-line continuous data were usually limited to only one or two parameters. Since the out set of this program over, 120,000 hour of real time data has been collected across a wide variety of different distribution systems exhibiting different water matrix profiles revealing many interesting attributes of the distributio systems. These systems represent a wide diversity of water quality conditions and operational

situations. The site locations need to remain anonymous due to security considerations and nondisclosure agreements but, they represent a wide diversity of system sizes and geographic locations throughout the United States. The deployments are at both civilian and military sites. The following are a few examples of incidents that have been recorded during these real world deployments. These incidents help to demonstrate the systems ability to learn and to become a useful tool not just for security but also for every day operational improvements.

A Chlorine Upset Event

A water panel distribution monitor and an event monitor were installed at a location in a major east coast city just down stream from a water storage tank. The event monitor recorded a regular alarm. See Figure 8.

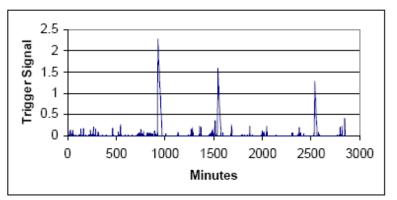

Figure 8: East Coast Location Showing Regular Alarm Events

Careful evaluation of the baseline parameter data showed that the alarms were being triggered by a chlorine upset. The chorine levels would gradually rise over time and then suddenly drop. It was this sudden drop that was triggering the alarm. See Figure 9.

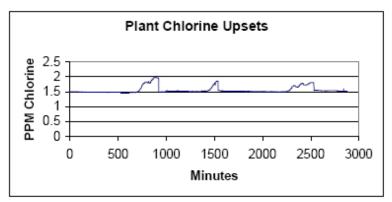

Figure 9: Chlorine Readings Caused the Trigger

Further investigation revealed that these upsets were due to the fact that the storage tank was normally filled from water source A, but at times of peak demand both source A and source B were turned on to fill the tanks. Source B has a higher chlorine residual than source A, therefore, when it is used to fill the tank the chlorine level slowly creeps up. When source B is turned off, due to hydrodynamic short-circuiting, the chlorine level drops rapidly to the concentration of source A. This rapid drop to the level of A was adequate to cause an alarm trigger. After this was determined the learning capability of the algorithm was used to name and classify this event as benign, so, when it occurred again the alarm was recognized. The screen would report the event as Name: Pump Shut Off, Type: NORMAL.

The Strange Case of the Chlorine Spikes

In one field deployment scenario, the system was very quiescent and rarely came anywhere close to causing a trigger alarm to go off. Except, that every night at around midnight, the chlorine level would spike dramatically and cause an alarm. This was deemed very strange and extensive trouble shooting of the instruments and power supply revealed no abnormal conditions that could be causing the problem.

After a thorough investigation, the night operator for the treatment plant was queried about the strange chlorine response. His reply was that of course the system's chlorine level spikes every night at midnight that is when he super chlorinates the system just like he had been told to do. It appears that several years ago, when there was a pipe rupture in the system that may have allowed contamination to seep in, the night operator had been told to super chlorinate the system. Unfortunately, the operator was new at the time and the instructions were not explicit that the super chlorination should take place that night only. The operator had continued to perform the operation every night for years resulting in a huge unnecessary cost in chlorine. This situation was remedied and should result in substantial chemical cost savings in the future.

Caustic Overfeed Event

In this deployment scenario, the plant uses caustic feed to control water pH. The system experienced a trigger alarm that when investigated was identified as an operational problem that resulted in the feed of excess caustic. The result was that the overfeed affected the pH and the conductivity of the water, causing the Event Monitor to alarm. See Figure 10.

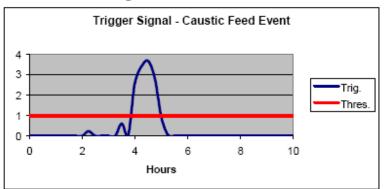

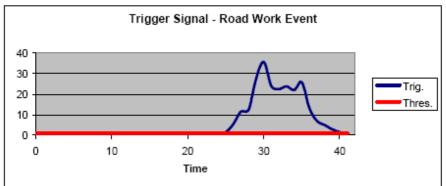

Figure 10: Caustic Event

The reason behind this was that the vendor from which the casuistic was being purchased had delivered the wrong concentration of the solution. No one had checked to see if the concentration was correct before feeding in the material. New procedures were put in place to

verify the identity and strength of chemical additives before addition to the treatment process. The Event Monitor learned this Plant Event and can identify a recurrence of the event in the future if there is another failure in the system and it is repeated.

Road Work Event

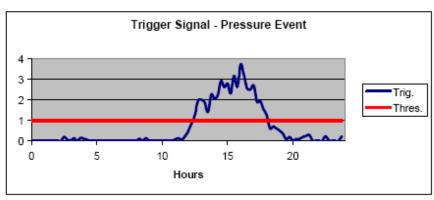

In this event, roadwork (jackhammers) near a distribution line dislodged biomass and other particulate matter from the lining of the pipe. There was a massive increase in turbidity, which not only showed up on the turbidimeter, but also showed up as an interference in the chlorine measurement (optical). As expected, the conductivity and pH also showed minor changes. The increase in biomass in the water was indicated by the TOC analyzer. See Figure 11. This event illustrates the ability of the Event Monitor to detect and alarm on unanticipated events. This event also provides a signature for the materials adhering to the walls of the pipes in this location and should recognize any future excursions of this type.

Pressure Event

In this scenario, the system was located in a building, which experiences a daily variation in water pressure. The sample variation is associated with a turbidity increase that causes a Trigger. See graph 5. There is also a small pH decrease at that time, possibly because of increased solubility of CO2 in the water, dropping the pH slightly. After recognition of the cause and proper naming of this pattern, it is recognized by the Event Monitor as a "Normal" event, rather than an alarm condition, and appropriately classified and named as such.

Main Break Event

In this situation the system had only just been installed a few days previously. Hach HST personnel were informed that the instruments were behaving abnormally and were giving strange readings. An investigation of the sensors found no problems. A short time later a major main ruptured in a catastrophic mode. See Figures 13 and 14. The system was able to detect the perturbation in water quality parameters that were precursors to the main break and trigger upon them. Unfortunately, the system was newly installed and the event was not recognized until it was too late. The system has memorized this pattern and hopefully if a similar situation arises it may be able to alert before the problem is out of control and a catastrophic failure occurs.

Figure 13: The system was able to detect water quality perturbations that were forerunners to this catastrophic main break.

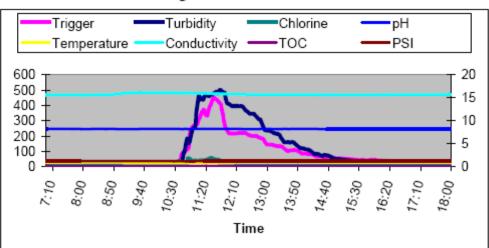

Figure 14: Main Break Event

Learning Ability

As has been previously indicated, the system is equipped with a learning algorithm, so that as unknown alarm events occur over time the system has the ability to store the signature that is generated during the event. The operator can then go into the program and identify that function and associate it with a known cause such as the turning on of a pump or the switching of water sources, etc. Then the next time that event occurs it will be recognized and identified appropriately. Over time, as the system learns, the probability of an unknown alarm that has not been previously encountered and classified will continue to decrease and will eventually approach zero. One point however that should be noted, is that as soon as the system is turned on, it will be actively working and will have the ability to trigger and classify immediately if the signature of a known threat agent is encountered. The probability of an unknown alarm due to a given event depends upon the frequency of the occurrence of such an event and the time that the algorithm has had to learn that event. Events that occur frequently will be quickly learned while rare or singular events will take longer to be learned and stored.

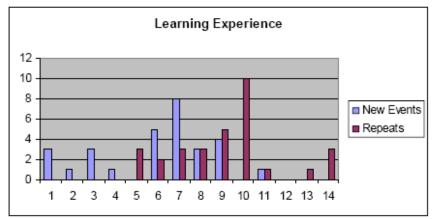

Figure 15: Learning Speed Demonstrated

The data in this case represent a real world deployment situation that had very noisy water quality. In this scenario, there were 26 unique trigger events in the first 11 days of operations. All were fingerprinted and learned by the system. 11 of the events were repeated. This demonstrates that common events are rapidly learned by the system resulting in a rapid decrease in unknown alarms. See Figure 15.

CONCLUSION

Extensive laboratory and pipe loop testing that is detailed in a separate paper indicate that these systems appear to be a good choice for detecting water quality excursions that could be linked to water security events. There are a number of advantages to using such systems. The chief advantage is that these instruments are not new. They are based on common everyday parameters that the average industry worker is quite familiar with, thus, adding a degree of comfort in operations not afforded by other new technology. As existing technologies, these instruments have been proven to be robust and dependable in prior field deployments. They represent measurements that would be of interest and use to water utility personnel above and beyond their role as water security devices. The testing detailed in this paper confirms this and also demonstrates the applicability of utilizing these everyday parameters by linking them with

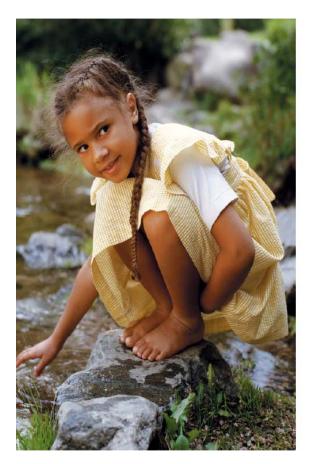

advanced algorithms. The field deployment studies not only demonstrate robustness in the field and the ability to recognize a wide variety of events, but these studies also demonstrate such system's ability to learn. It is foreseeable that these devices will become much more than a system that is capable of detecting terrorist events. They could easily become a critical tool for improving everyday operations.

For example, through many years of experience, the best old hands at treatment plant operations have developed "a sense" for knowing something in the treatment system is amiss. It can be a smell, color, clarity (or lack there of), sound or just tingling in the nape of the neck. One gains this sense only by extensive experience in a particular facility. These senses do not exist in distribution systems because there has typically been little measurement done upon which to gain these "senses" and, therefore; "Bulk Parameter Monitoring in the Distribution System with Interpretive Algorithms" has the potential to become the artificial "sense" able to quickly "learn" the quirks of the distribution system and have those quirks labeled by those with extensive experience so that less experienced employees have the benefit of that knowledge without having to wait 5, 10 or more years. A good phrase to describe this knowledge base would be "institutional intuition." (Kroll 2006) With the aging of the work force and rapid employee turnover "institutional intuition" has the chance of quickly dying out. Above and beyond their obvious security benefits, algorithms could be a way to circumvent this loss of knowledge and to build a knowledge base where none has previously existed. This in turn could allow improvements is system operation that may result in cost savings and definitely will result in a higher quality product being delivered to the consumer

Operational and Laboratory Verification Testing of a Heuristic Online Water Monitoring System for Security

By Dan Kroll, Karl King and Greg Klein

National Environmental Monitoring Conference

> August 27th-31st Arlington, Virginia

> > 1

If only it were this easy.

Distribution Systems are Vulnerable to Backflow Attacks

Statement of the Problem

3

4

- Can we use basic water quality sensors to spot deviations from normal in a distribution system, and then mathematically analyze the deviation signals to:
- TRIGGER when something harmful is present
- DETECT what agent is present, and
- QUANTIFY the amount in the water?

The conventional wisdom is that this cannot be done.

Sensor set selected

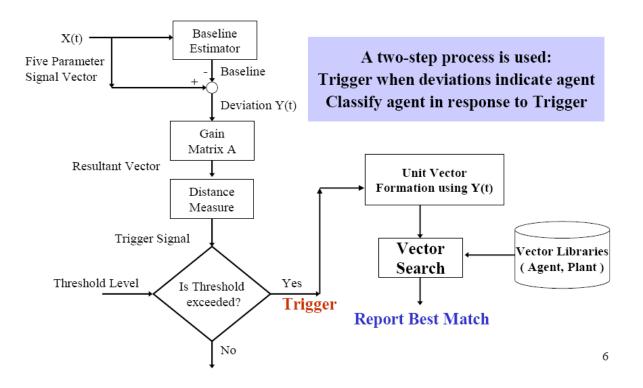

- pH acid/base relationships
- Electrolytic Conductivity ionic concentrations
- Chorine disinfectant levels, oxidant reduction
- Turbidity particles in water (bio agents)
- Total Organic Carbon carbon content of organic molecules

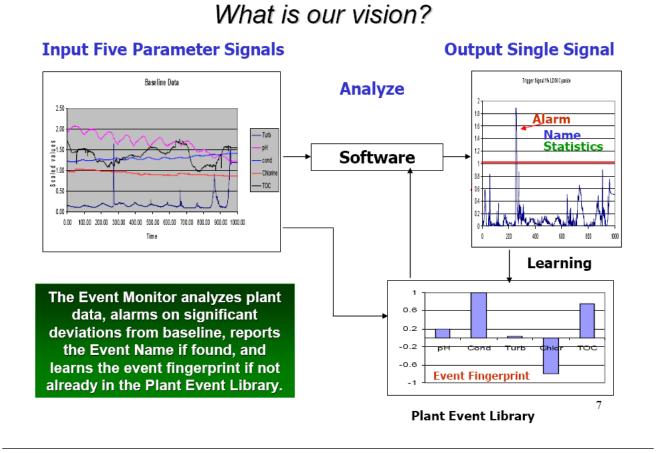

ORP – NOT SELECTED because it is unstable and prone to poisoning in long-term installations

Sensors were selected for reliability and ability to measure fundamentally different characteristics of threat agent substances.

Detection Algorithm added to Trigger

Beaker Testing What Can We See?

Testing at the Hach Loveland, Colorado facility on a variety of agents: Over 80 Agents Characterized so far.

Pesticides and Herbicides Including Organophosphates and Carbamates, Biotoxins, Bacterial Cultures, Heavy Metals, Cyanides, Street Drugs, Treatment Chemicals Such as Fluoride, Exotic Agents, Toxic Industrial Chemicals, Common Accidental Agents Such as Diesel Fuel and Antifreeze.

Beaker Testing at ECBC

- Fingerprints for all agents developed in a variety of matricies
- ROC curves prepared
- Transfer to real world scenario verified by selected loop testing.

• Trigger level varied form 0.36 to 1.36

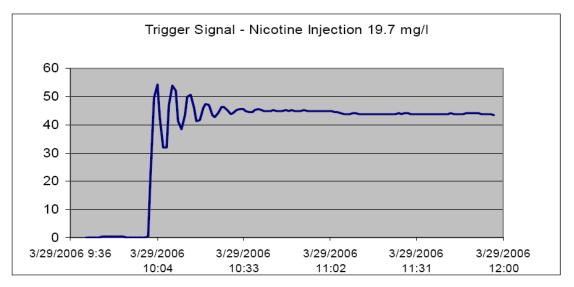

35

Loop Testing at ECBC

• Warfare and threat agents with disposal and handling problems such as Nerve agents and biotoxins are tested on a closed loop system to prevent loss of the agent to the environment.

37

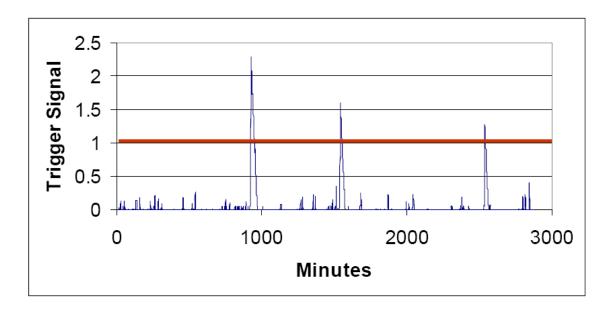

The test concentration of nicotine was 19.7 mg/L. In a single test run, nicotine was recognized by the system, with detection angles ranging from 0.94 degrees (essentially a perfect match) to 9.84 degrees (a weak match). The fluctuating trigger signal is due to the mixing dynamics of a recirculating loop.

Real World Deployment

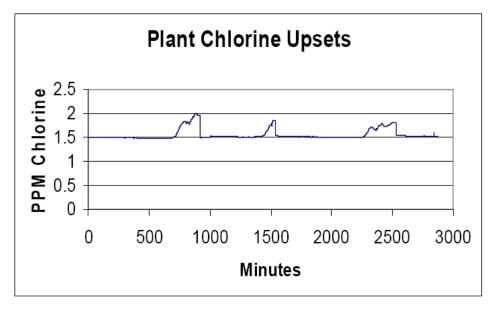

- Over 120, 000 hours of real world data generated and analyzed so far.
- Various sites throughout the United States
- Demonstrates ability to learn common events and respond to abnormal activities.

East Coast Location Near Water Storage Tankalarm triggered .

40

Plant Event Defined Name: Pump Shut Off, Type: NORMAL

41

Learning Method for Plant Events

Without learning, the system sees a False Alarm each time a benign event occurs.

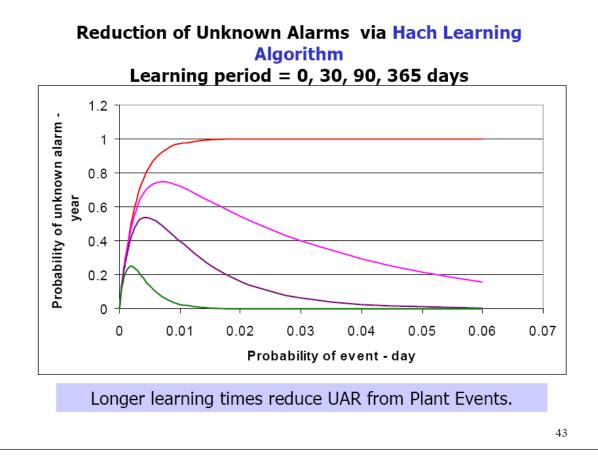

With learning, the probability of a false alarm is reduced.

P(false alarm) = P(not learned)*P(event)

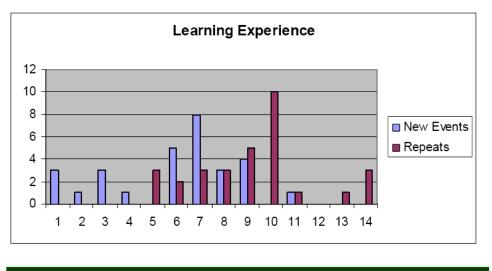

Over time, P(not learned) goes from 1 to zero.

Learning recurring events reduces the False Alarm Rate

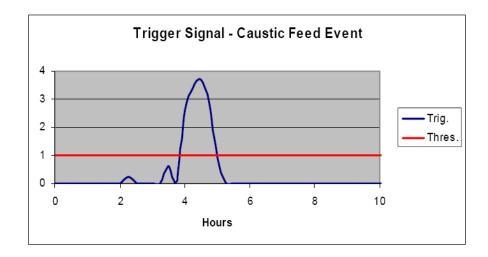

42

Results of Learning at a Very Noisy Location

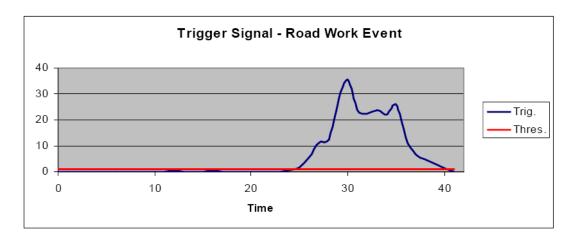

There were 26 unique events over 11 days of operation. All were learned, 16 of them were repeated. 22nd Annual National Environmental Monitoring Conference

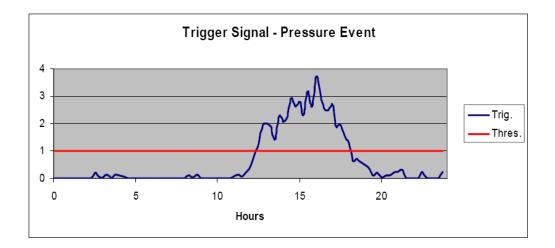

The plant uses caustic feed to control water pH and experienced an operational problem that resulted in the feed of excess caustic. That affected the pH and the conductivity of the water, causing the Event Monitor to alarm. The Event Monitor learned this Plant Event and can identify a recurrence of the event.

45

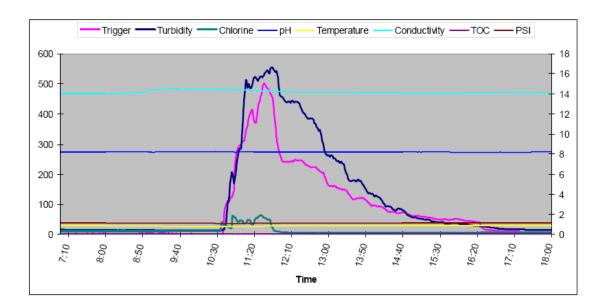

Road work near a distribution line dislodged biomass and other particulate matter from the lining of the pipe. There was a massive increase in turbidity, which not only showed up on the turbidimeter, but also showed up as an interference in the chlorine measurement (optical). As expected, the conductivity and pH also showed minor changes. The increase in biomass in the water was indicated by the TOC analyzer. This event illustrates the ability of the Event Monitor to detect and alarm on unanticipated events. This event also provides a signature for the materials adhering to the walls of the pipes in this location.

The Event Monitor is located in a building which experiences a daily variation in water pressure. The sample variation is associated with a turbidity increase that causes a Trigger. There is also a small pH decrease at that time, possible because of increased solubility of CO2 in the water, dropping the pH slightly. This pattern is recognized by the Event Monitor as a "Normal" event, rather than an alarm condition.

47

Pennsylvania Event

Pittsburgh 36 Inch Main Break

• A geyser caused by a severed 36-inch water line erupts from Fort Duquesne Boulevard at about 10:30 a.m., August 17th. One of the largest water main breaks in the city's modern history.

A driver who was able to rescue a vehicle follows a man on foot out of a flooded Gateway Center parking garage, following a water main break on Fort Duquesne Boulevard.

More than 20 million gallons of water poured out of Fort Duquesne Boulevard and into nearby parking garages and other low-lying areas Downtown yesterday morning.

51

 Workmen do preliminary work
 before the 36 inch main could be repaired on Fort Duquesne
 Boulevard Workers move a section of new pipe into position as the broken 36-inch water main can be seen in the background.

- Effective distribution system monitoring provides significant benefit to operational management
- Taken in aggregate, with interpretive software, an appropriate group of on-line sensors can identify deviations from normal water quality in the distribution system
- Data analysis does require advanced interpretive algorithms to help separate the normal from the abnormal
- Creating a multi-dimensional monitoring network provides a robust system allowing managers to be on top of issues and changing conditions before customers experience them
- We are continuing our development efforts to extend the application of the Event Monitor Trigger System to also include a real-time security monitoring solution

The earlier you have systems installed, the more Plant Events you will observe for the algorithm to learn from ... the larger the data set, the fewer unknown events you will see.

Questions?

HAND-PORTABLE TOROIDAL ION TRAP DETECTOR FOR HOMELAND SECURITY

Contreras, Jesse A. – Brigham Young University; Lammert, Stephen A. – Brigham Young University; Lee, Edgar D. – Palmar Technologies; Lee, Milton L. – Brigham Young University; Murray, Jacolin A. – Brigham Young University; Oliphant, James R. – Palmar Technologies; Tolley, H. Dennis – Brigham Young University; Tolley, Samuel E. – Palmar Technologies

There is an increasing demand for hand-portable instrumentation for detection of target chemicals in defense and homeland security operations. The requirements of such instrumentation include robustness, and small size and weight, in addition to the universally sought virtues of sensitivity, selectivity, and speed. A hand-portable gas chromatograph-mass spectrometer (GC-MS) system is attractive for this application because of its unmatched selectivity and sensitivity for a variety of target compounds. The MS reported in this paper is a novel, miniature toroidal RF ion trap that can be operated at RF voltages significantly lower than required for conventional traps. The large trapping volume characteristic of the toroidal geometry allows miniaturization while still preserving high sensitivity. The miniaturized ion trap provides unit mass resolution. A low thermal mass GC with 5 m x 0.10 mm i.d. capillary column provides rapid analysis with low power consumption. Helium mobile phase is supplied by a small pressurized gas cartridge. Sample introduction is based on solid phase micro extraction (SPME), which can be applied to a variety of sample matrices. A new SPME syringe with identification chip was developed for one-hand operation. The complete system weighs approximately 8.2 kg (including batteries) and has a volume of 0.014 m³. A typical analysis for chemical agents and simulants can be completed within 3 minutes.

Hand-Portable GC-MS for CBA Detection

The 22nd Annual National Environmental Monitoring Conference Arlington, Virginia August 28—31, 2006

Douglas W. Later, Milton L. Lee, Stephen A. Lammert, and Edgar D. Lee

Rationale for Approach

- Use proven technologies
- Reduce size of technologies
- Combine in multidimensional arrangement
- Use smart information—sorting algorithms
- Provide easy operation

Proven Technologies

- Solid Phase Microextraction (SPME)
- Gas Chromatography (GC)
- Ion Trap Mass Spectrometry (ITMS)

Confidential

CB007 Hand-portable GC-MS

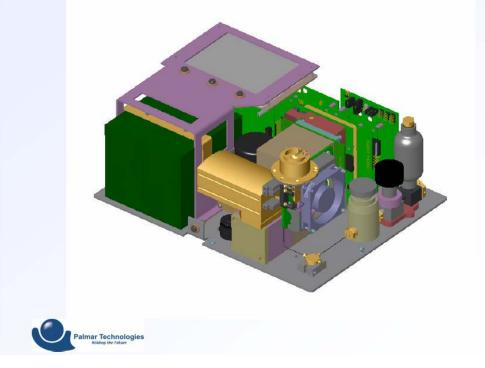

- Dimensions: 13 x 10 x 6 inches
- Weight: < 20 lbs (including batteries)
- Power:
 - Battery operated (12/24 VDC)
 - AC Power Adaptable
- Easy to operate

Palmar Technologies Rouking the Fature

Hand-Portable GC-MS Solid Model

Hand-Portable GC-MS Solid Model

Why Mass Spectrometry?

- GC/MS is the legal and laboratory standard for chemical identification
- High sensitivity and high selectivity (especially using GC inlet)
 - High Sensitivity ⇒ Low false negative rates
 - High Selectivity ⇒ Low false positive rates

Much higher selectivity than spectroscopic techniques or ion mobility spectrometry (i.e., molecular weight, fragment ions, relative intensities vs. one ion mobility value)

Palmar Technologies Histories de Fature

Why Ion Trap Mass Spectrometry?

- Simple, rugged design (no critical alignment ion optics)
- Tolerant of low vacuum conditions (<u>requires</u> 1 mtorr operating pressure ⇒ less stringent vacuum requirements
- MS/MS and MSⁿ capability in one mass analyzer
- High duty cycle ⇒ high sensitivity
- Low power (especially with small ion trap mass analyzers)

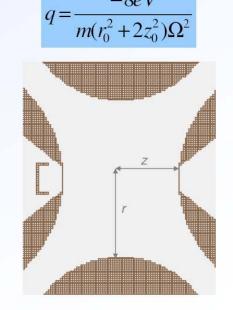

Ion Trap Constraints

- 3-D ion trap is an "ion bottle" with somewhat fixed relative dimensions (r₀ vs. z₀)
- Ion-ion repulsion (space charge)
- Commercial traps optimized at

 $r_0 = 1 \text{ cm}, \sim 16 \text{ kV}_{p-p}$

Palmar Technologies

- Further increase in r₀ not practical due to arcing of rf high voltage
- Decrease of r₀ yields lower rf power, but will lead to earlier onset of space charge

Approaches to Address Space Charge in Small Ion Traps

(1) Arrayed, reduced r₀ cylindrical ion traps

Simple to machine, but ion capacity must be recovered by increasing the number of trapping cells in an array

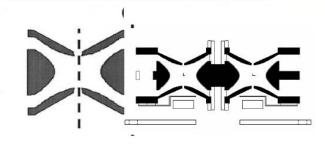

(2) Alternative Geometries

Increased ion storage using different IT geometries

- Linear IT
- Toroidal IT

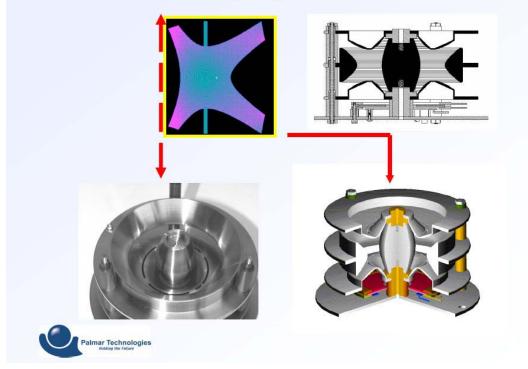

Rotations of IT Cross-Section

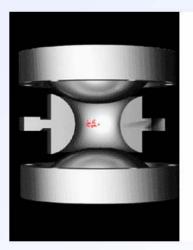

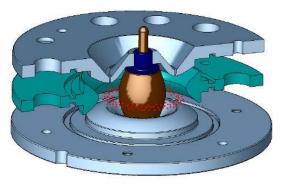

Toroidal RF IT (Asymmetric Corrections)

Ion Storage Volume

Why Toroidal RF Ion Trap Mass Spectrometry?

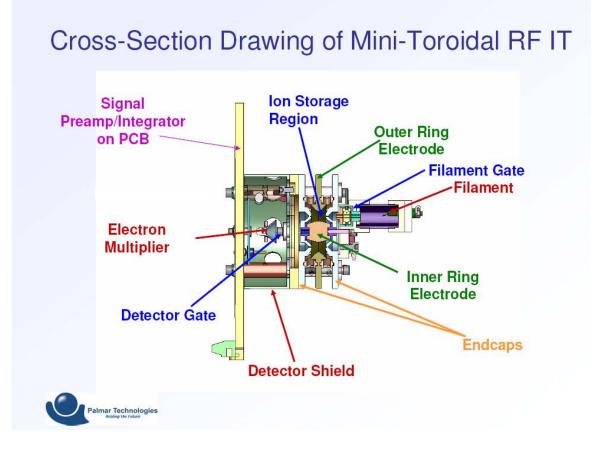

- Single mass analysis volume (compared to arrayed miniature cylindrical ion traps)
 - All ions experience the same trapping/mass analysis field
 - Easier coupling to ionization and detection optics
- Compact geometry (compared to linear ion traps of similar storage capacity)
- Homogenous field (compared to linear ion traps)
 - No end effects. All spatial positions within mass analyzer are equivalent

Palmar Technologies

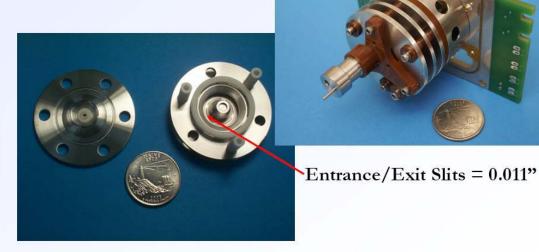

Mini-Toroidal RF IT Design

- Small toroidal geometry
 - $-r_0 = 2 \text{ mm}; \text{R} = 6 \text{ mm} (\text{R}/r_0 = 3)$
 - Voltage requirement reduces by ~ r₀²
- Custom electron gun designed to provide a gated e⁻ beam through a small portion of the entrance endcap slit
- Custom electron multiplier (DeTech)
 - Operation with >10⁵ gain at pressures as high as 10⁻² mbar

Palmar Technologies Roading the Fature

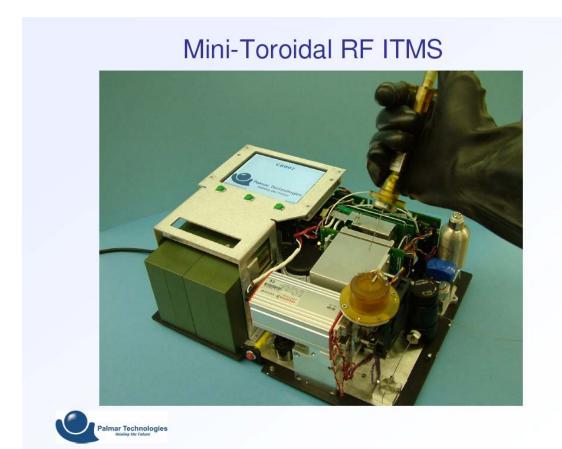

Electrodes and Analyzer Assembly

Prototype CB007 GC-ITMS Systems

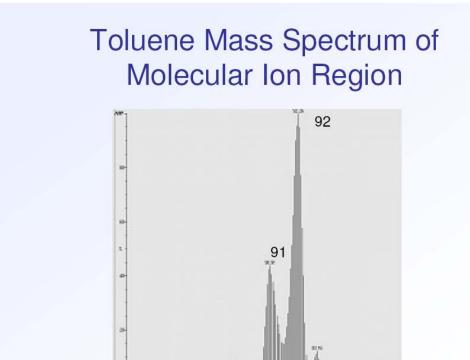

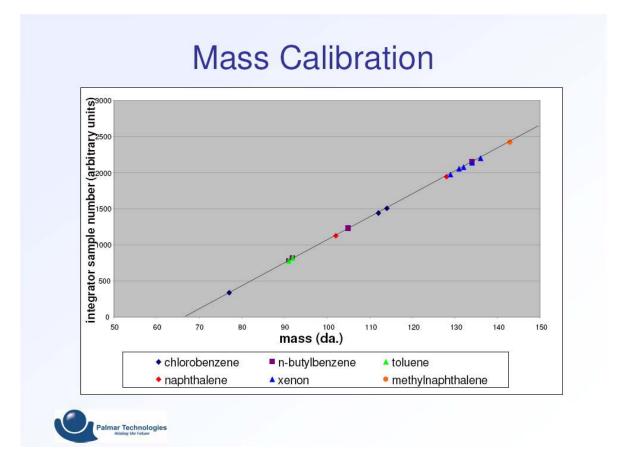

Operating Parameters

- RF trapping field:
 - 1.9 MHz, ~200-1200(max) V_{p-p}
 - Amplitude scan (linear), 200 ms scan
- Resonance ejection frequency:
 - ~900 KHz, approx. 4 V amplitude
- Ionization:
 - Typically 10-100 ms
 - Gated focusing lens assembly on electron gun and detector
- Pressures:
 - Sample: typically between 1 x 10⁻⁶ and 4 x 10⁻⁵ mbar (uncorrected)
 - Helium buffer gas: typically 2-4 x 10⁻⁴ mbar (uncorrected)

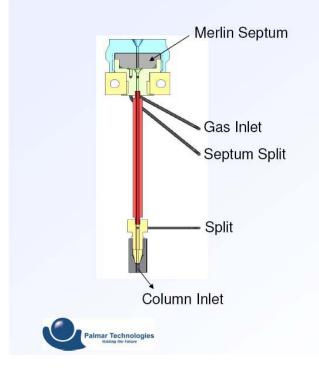

Palmar Technologies

Low Thermal Mass SPME Injector

Low Thermal Mass (LTM) GC Assembly

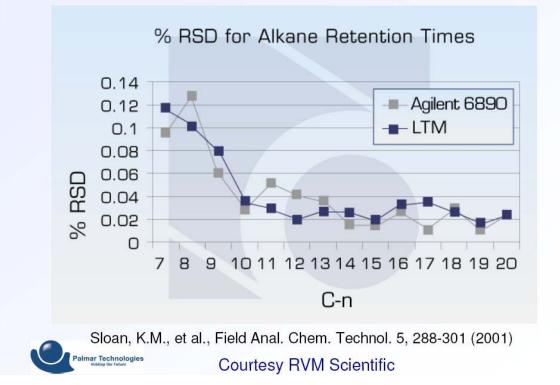

LTM GC Features

- Most efficient GC technology for temperature programming
- Compatible with wide range of temperature programs
- Any capillary column in any length
- Fast cool down rate
- Any laboratory temperature programming method can be run with only 1% of the power compared to laboratory instrument

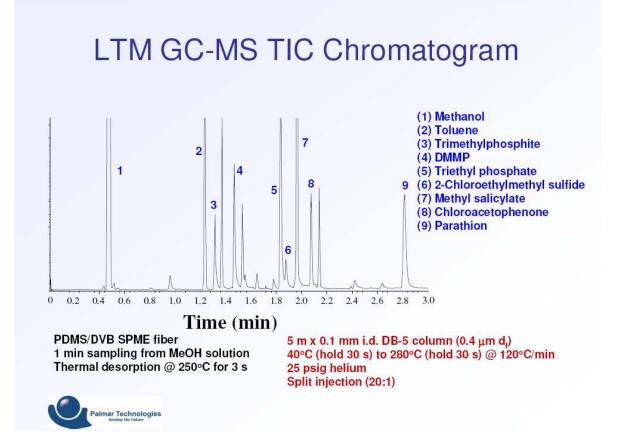

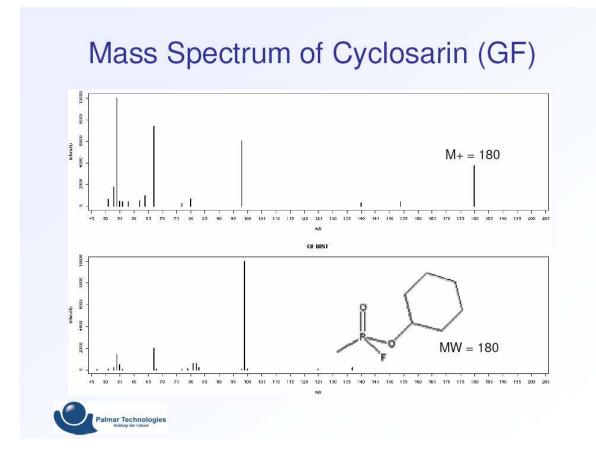

LTM GC Retention Time Reproducibility

Spectral Factorization Algorithm

- Extract relevant spectra from data matrix
- Calculate correlations to target library
- Identify matches
- Fast
- Mathematically sound
- Numerically stable
- · Chemically sensible

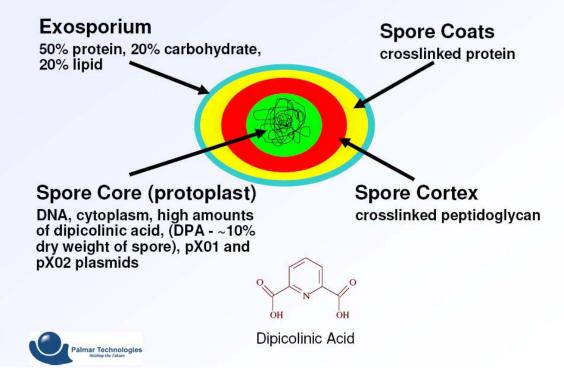

Palmar Approach to Bacterial Threat Detection

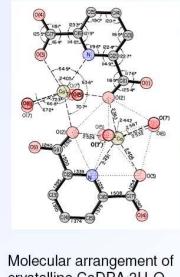

- Catalytic generation of volatile/semi-volatile biomarkers
 - Better control of conditions and reactions
 - Preservation of biomarker structures
 - Lower temperature than pyrolysis
- Multidimensional chemical analysis
 - GC-MS
- Multiple biomarker classes
 - Dipicolinic acid
 - Fatty acids
 - Aromatic amines
 - Carbohydrates
- Powerful deconvolution/classification algorithms

LABORATORY CAPABILITY IN SUPPORT OF EMERGENCY RESPONSE

Fitz-James, Schatzi; U.S. Environmental Protection Agency

Last year, Agency representatives presented a session regarding plans to address laboratory needs in the event of a terrorist incident. In the event of an actual or suspected terrorist incident, comprehensive laboratory resources will need to be called upon to allow the nation to deal with any situation. Over the past year, the federal Integrated Consortium of Laboratory Networks (ICLN) has formed and begun to address national analytical capabilities for chemical, biological and radiological contaminants of concern in clinical, food, plant and environmental media.

The President's National Homeland Security Strategy calls upon EPA to be the primary agency responsible for environmental sampling and analyses in response to a terrorist incident. In response to this strategy, and in concert with the Agency's role in the ICLN, an environmental laboratory response network program (eLRN) is in the formative stages in the Office of Emergency Management, Office of Solid Waste and Emergency Response at EPA Headquarters.

EPA possesses limited capabilities and capacities to analyze environmental samples for chemical, biological and nuclear materials associated with Weapons of Mass Destruction (WMD). The eLRN is exploring approaches to address this limitation. The Agency's primary analytical capability is oriented toward routine analysis of industrial chemicals, pesticides, and conventional pollutants. The first phase of the eLRN will be to formalize network relationships using these pollutants as the model. Later phases will integrate biological and radiological materials into the eLRN. EPA also intends to fully integrate state public health/environmental laboratory counterparts into the eLRN similar to the integration utilized in the other networks.

A brief history of the ICLN and the associated networks will be discussed, as well as a summary of the past year's activity. The structure, approach and status of the eLRN will also be presented.

The eLRN approach will continue to follow the precepts below:

- to the extent possible, make use of the nation's current laboratory resources
- address the problem in the most cost-effective manner
- develop a solution as quickly as possible

Organic Methods

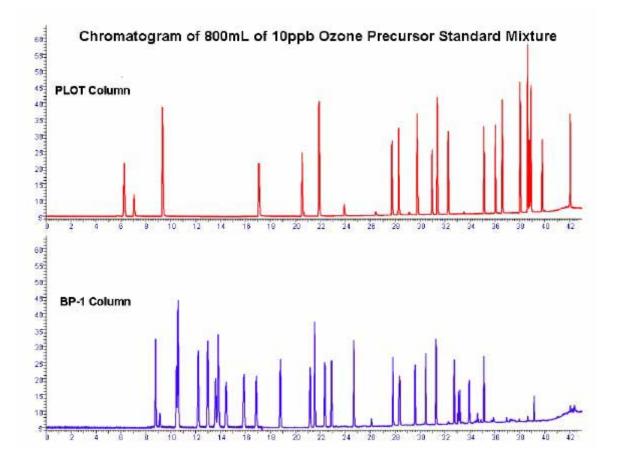

RECENT ADVANCES IN THERMAL DESORPTION

Grosser, Zoe; PerkinElmer Analytical Sciences Tipler, Andrew; PerkinElmer Analytical Sciences

Environmental air analyzers require rugged and precise performance. Some of these systems must be run unsupervised in remote locations and so full access is needed to the operational aspects of the system.

In this paper we describe the development of a fully automated air analyzer based on thermal desorption (TD) and gas chromatographic (GC) instrumentation. A critical requirement for this system was the provision of electronically programmable pneumatic controls (PPC) throughout. Such controllers are less susceptible to drift than manual pneumatics and are ideal for long term unattended operation.

This analysis involves the sub-ppb determination of volatile organic compounds (VOCs) known to promote the formation of ozone in atmospheric air. These VOCs are essentially alkyl hydrocarbons and aromatics that cover the carbon range C2 to C11. Air to be analyzed is drawn at a controlled flow rate and for a metered time through a cooled adsorbent trap. A Nafion drier is used to remove moisture from the sample before it enters the trap. The trapped analytes are thermally desorbed and carried by carrier gas supplied by a PPC device into a GC. The GC uses a Dean's switched heartcut device to separate analytes by volatility between two columns of differing retention to effect a parallel chromatographic separation. By using a PPC controller to supply carrier gas to the heartcut device, setup of the necessary pressure-balanced conditions is very straightforward and, once set, the conditions do not need further adjustment during normal use. Programmable pneumatic controllers are also used to supply the two flame ionization detectors on the GC system. The figure shows example chromatography from this system. Further data will be presented to demonstrate the ruggedness and precision of the instrumentation.

Recent Technical Advances in Thermal Desorption – Gas Chromatographic Instrumentation for Fully Automated Ozone Precursor Analysis

Andrew Tipler, and Zoe Grosser PerkinElmer LAS

ABSTRACT

Environmental air analyzers require rugged and precise performance. Some of these systems must be run unsupervised in remote locations and so full access is needed to the operational aspects of the system.

We describe the development of a fully automated air analyzer based on thermal desorption (TD) and gas chromatographic (GC) instrumentation. A critical requirement for this system was the provision of electronically programmable pneumatic controls (PPC) throughout. Such controllers are less susceptible to drift than manual pneumatics and are ideal for long term unattended operation.

This analysis involves the sub-ppb determination of volatile organic compounds (VOCs) known to promote the formation of ozone in atmospheric air. These VOCs are essentially alkyl hydrocarbons and aromatics that cover the carbon range C₂ to C₁₁. Air to be analyzed, is drawn at a controlled flow rate and for a metered time, through a cooled adsorbent trap. A NafionTM drier is used to remove moisture from the sample before it enters the trap. The trapped analytes are thermally desorbed and carried by carrier gas supplied by a PPC device into a GC. The GC uses a Deans' switched heart-cut device to separate analytes by volatility between two columns of differing retention to effect a parallel chromatographic separation. By using a PPC controller to supply carrier gas to the heartcut device, setup of the necessary pressure-balanced conditions is very straightforward and, once set, the conditions do not need further adjustment during normal use. Programmable pneumatic controllers are also used to supply the two flame ionization detectors on the GC system. Data is presented that demonstrates the performance of the instrumentation.

INTRODUCTION

Hydrocarbon vapors (known as ozone precursors) in the troposphere react in the presence of nitrogen oxides (NO_X), carbonyls, etc. and in the presence of UV from sunlight, to create ozone. Such reactions become apparent as haze above urban areas during hot sunny weather.

Ozone is poisonous and will also readily react with other organic vapors to produce other toxic vapor species with long half-lives. The persistent presence of these vapors in the air that we breathe has become a major concern in many parts of the world and there is now a strong need to measure and ultimately *control* the emissions of these compounds.

In the United States, the Clean Air Act of 1973 mandated the monitoring and control of NO_x , SO_x , CO, PM, Pb and O₃ in the atmosphere. To this end, the US-EPA introduced a method of analysis [1] to monitor levels of over 50 organic compounds in ambient air known to promote the formation of ozone as listed in Table 1.

Ethane	2-Methylpentane	Ethylbenzene

Table 1: Analytes Listed in US-EPA Technical Assistance Document

The work presented here describes a system that fully automates this analysis to enable continuous results to be collected at field locations.

Several key requirements for the analytical system have been requested by the US-EPA* and these are listed in Table 2.

requirements for an obolic freedoor fundysi
No use of liquid cryogen
Unattended Operation
Chromatography of all analytes in single run
Hourly sampling
Simultaneous sampling and chromatography
Automatic system calibration
Full data processing
Full remote control of system
Automatic data archival

Table 2: Key Requirements for an Ozone Precursor Analysis System

* Cooperative Research and Development Agreement between US-EPA and PerkinElmer, 1991

SYSTEM DESCRIPTION

The system described here that fulfils the analytical requirements comprises three primary components:

- A thermal desorption system that collects and concentrates the vapors from the atmosphere being monitored and injects them into the gas chromatograph. It also manages the timing of the sampling and analytical processes.
- A gas chromatograph that performs the separation and detection of the collected vapor compounds.
- A data processing system that generates the results and provides access to the system from a remote location.

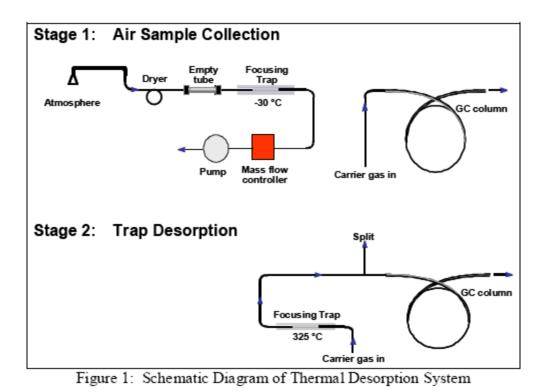

Thermal Desorption System

The function of the thermal desorption system is illustrated in Figure 1. The analytical system is placed close to the sampling location. Ambient air is drawn through a tube connected to the thermal desorption system. A vacuum pump is connected to an outlet on the thermal desorption system. During sampling, the vacuum pump will draw ambient air through a Peltier-cooled adsorbent trap at -30°C which will retain all analytes listed in Table 1. Modern adsorbents that are cooled to this temperature are very capable of retaining the C₂ analytes without recourse to liquid cryogen. An electronic mass flow controller, which is connected between the trap and the vacuum pump, regulates the rate of air flow through the trap to a user-entered value which is typically 15mL/min. A NafionTM dryer (DuPont) is used to remove moisture from the air stream before it reaches the cold trap. The system will continue to sample the air for a period of time entered by the user - typically 40 minutes. Once sampling is complete, the trap is rapidly heated to an elevated temperature to desorb the analytes which are then carried by helium carrier gas, via a fused silica transfer line to the gas chromatographic column. To ensure optimum peak shape of the early eluting compounds, a small split (typically 3 to 5mL/min) is applied between the trap and the GC column.

An electronic programmable pneumatic controller is used to regulate the carrier gas pressure into the GC column. Besides facilitating easier setup, the carrier pressure is less likely to drift than conventional manual pneumatic systems over the long periods of time over which this analysis is performed.

The system is designed so that the sampling plumbing is independent of the carrier gas flowing into the GC column. This enables sampling of the next sample to commence during the chromatography of the current sample. In this manner, samples may be collected and analyzed every chronological hour.

The thermal desorption control functions manage the timing of the sampling and analysis.

A new feature developed for this system is the ability to monitor the impedance to flow through the adsorbent trap. Technology has been developed to measure the pressure drop across the trap during operation so that the physical integrity of the trap can be ensured. If the pressure drop suddenly changes as a result, for instance, of movement of the packing, the system can be made to automatically stop. Figure 2 shows measurements made on a single trap over an extended run of samples.

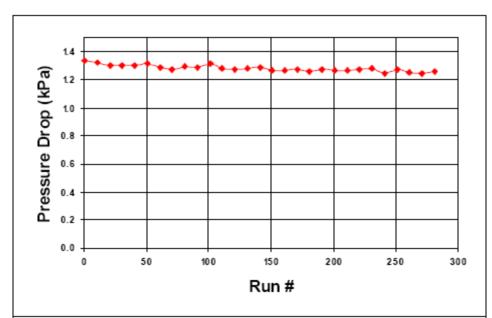

Figure 3: Monitoring the Trap Integrity by Measuring the Pressure Drop Immediately Before each Analysis

Gas Chromatograph

While the Peltier cooled trap on the thermal desorption system effectively eliminates the need for liquid cryogen in the sample collection process, attention must be given to ensure that the need for liquid cryogen is eliminated from the chromatography.

The gas chromatography of the analytes listed in Table 1 is particularly demanding and it would be difficult to perform a separation on a single column without resorting to sub-ambient operation.

To obviate this need, two columns of dissimilar retentiveness are deployed in a Deans' switched heart-cut configuration [2] as shown in Figure 4.

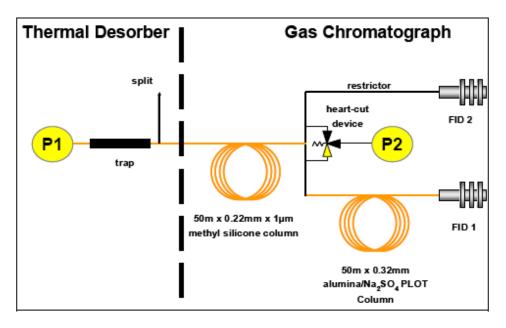

Figure 4: Schematic Diagram of 2-column Configuration with Deans' Switched Heart-cut Device

Initially, as the vaporized analytes are carried from the thermal desorption system to the gas chromatograph, they are passed into a methyl silicone column. The heart-cut device directs the effluent of this first column to a second, more retentive, PLOT column. The PLOT column will separate the C_2 to C_6 analytes at a temperature above ambient and these will be detected on a flame ionization detector. Once these analytes have passed into the PLOT column, the heart-cut device directs the effluent from the methyl silicone column to a second flame ionization detector and the remaining analytes up to C_{11} are detected. In this manner, the sample is effectively split into two fractions of differing volatility that are chromatographed in parallel on the two detectors. Figure 5 shows an example of the typical chromatography produced by this system. A full separation of C_2 to C_{12} (C_{12} is added as a marker) is obtained in about 45 minutes with an initial programmed temperature of 45°C and so totally eliminates the need for liquid cryogen to cool the GC oven.

A programmable pneumatic controller regulates the carrier gas pressure within the heart-cut device – again to simplify setup and minimize long term pressure drift.

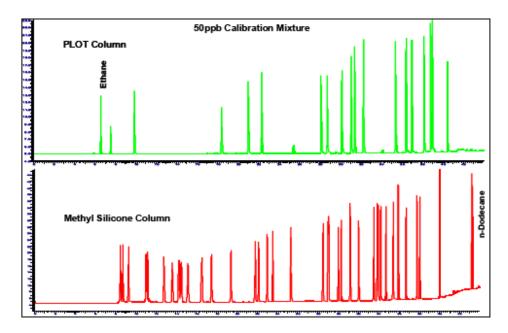

Figure 5: Parallel Chromatography of Analytes from Table 1 on a 2-column Heart Cut System Programmed from 45°C

Data Handling

The third key system component is the data handling system. This not only identifies and quantifies the chromatographic data but it also provides the control of the gas chromatograph and the thermal desorption system. This approach gives the user a single interface to the system control and status and to the analytical data. Because this software is PC based, third party tools may be used to access these function by telephone or internet. This allows users to collect data and check status remotely and eliminate unnecessary field site visits.

RESULTS

Table 3 gives some example analyte peak retention time and area precision and linearity from the system described previously. The conditions given in Table 4 were used to perform this analysis.

Table 5. Precision and Emeanly Data for Typical Analytes

CONCLUSIONS

Ground level ozone has become an increasingly important issue in developed nations, as the health effects of smog are more clearly understood. The monitoring of VOC ozone precursor compounds will continue to play a role in defining and reducing air pollution in developed and developing nations in the next decade.

The PerkinElmer Ozone Precursor Analyzer has a proven record of several hundred thousand hours reliable field operation. With quantification limits below 1 ppb and the capability of sampling for 40 minutes of every hour, the system meets the requirements of this exacting method.

The new systems described here are based on these established technologies and bring the additional benefits of electronically programmed pneumatic controls for ease of use and stability and trap integrity testing for increased confidence in the analysis.

EPA Quantification of Low Molecular Weight Alcohols, Ketones and Ethers using Headspace Trap - GCMS

William Goodman, Heidi Grecsek

PerkinElmer LAS

ABSTRACT

Low molecular weight alcohols, ketones, and ethers are of increasing interest to environmental monitoring programs nationwide. In environmental samples, these compounds provide unique analytical challenges as a result of their high miscibility and solubility in water. Utilizing headspace trap as a sample introduction technique for GCMS analysis provides the laboratory with many advantages over traditional techniques. The headspace trap uses heat to extract (partition) the compounds from the sample into the headspace, this headspace is focused onto an adsorbent trap and rapidly transferred to the GC column.

Headspace trap technology provides laboratories the benefits of static headspace sampling, (no carry-over, no cross-contamination, no foaming, and ease of sample preparation) along with the detection limit improvement of a trap allowing a 80x to 100x improvement in sensitivity. This technology is capable of sampling the entire headspace, utilizing a pulsed pressure headspace extraction process followed by refocusing on an adsorbent trap. Additionally, headspace trap has the ability to extract analytes, while interferences remain in the sample matrix.

Presented will be quantitative results and detection limits for a list of low molecular weight alcohols, ketones, and ethers. Results including linearity, precision, and detection levels will be discussed.

INTRODUCTION

Low molecular weight alcohols, ketones, and ethers are of increasing interest to environmental monitoring programs nationwide. In environmental laboratories, it is with increasing frequency that these compounds are included in standard volatile organic analysis, under EPA method 8260. In environmental samples these compounds provide unique set of analytical challenges as a result of their high miscibility and/or solubility in water. Utilizing headspace trap as a sample introduction technique for GCMS analysis of fuel oxygenates provides the laboratory with many advantages over traditional techniques.

The Clean Air Act amendments of 1990 require that oxygenated compounds be added to gasoline to produce fuel with increased oxygen content. A number of different compounds can be used to oxygenate fuel, a list of the most common are: methyl-tert-butyl-ether, tert-amyl-methyl-ether, ethyl-tert-butyl-ether, tert-butyl alcohol, and ethanol. Oxygenated fuel is desirable because it burns more completely, thereby reducing tailpipe emissions. Currently, the most commonly used fuel oxygenate additive is methyl-tert-butyl-ether (MTBE). MTBE receives much scrutiny as a result of its widespread use as a fuel oxygenate and as a result of environmental concerns surrounding it. As a result of this some states are phasing out MTBE as a gasoline oxygenate.

The transportation, transfer, and storage of oxygenated fuel in underground tanks present an environmental a risk. Leaks and spillage can contaminate ground, surface, and waste waters; creating a significant opportunity for releases into the environment. The polar nature of fuel oxygenates creates contamination plumes that spread quickly and are difficult to control and remediate. Ground and surface water polluted with MTBE and other fuel oxygenates is widespread and poses a potential threat to human health.

The regulation of MTBE and the monitoring of other fuel oxygenates has created a need for a simple, robust, and reliable method to analyze low molecular weight alcohols, ketones, and ethers, in environmental samples. These compounds pose a series of challenges to traditional organic volatile analysis techniques, including poor purging efficiencies, cross contamination, and foaming. The headspace trap technique uses heat to extract (partition) the compounds from the sample into the headspace improving recoveries for many compounds that traditionally do not purge well. Additionally, the risk of contamination is dramatically reduced as the sample never contacts the instrumentation.

EXPERIMENTAL

Headspace Trap Theory and Technology

Headspace is a very well established sample introduction technique for GC analysis of volatile organic compounds. The use of headspace in environmental laboratories is limited by the need for lower detection limits. The combination of headspace with another very well established technique, thermal desorbtion, has allowed it to become applicable to the low level analysis demanded by the environmental industry today. To completely understand Headspace - Trap we must first look at classical (static) headspace. Within a headspace vial exists a partitioned system in which equilibrium must be met, equilibrium depends on the temperature of the system, the volume of the gas phase, and the volume of the sample phase. If the temperature, sample volume, and vial volume are constant you will have a number (K) that will directly describe the ratio a compound between the gas (headspace) and sample phase (equation 1).

Equation 1: Partition Coefficient $\mathbf{K} = \mathbf{C}^{l}/\mathbf{C}^{g}$ $\mathbf{K} = Partition coefficient of a volatile$ $<math>\mathbf{C}^{l} = Concentration in the liquid phase$ $\mathbf{C}^{g} = Concentration in the gas phase$

Headspace analysis works best for compounds with low partition coefficient. A low partition coefficient represents a compound with a high concentration in the gaseous phase relative to its concentration in the liquid phase. If the temperature of the system is increased the partition coefficient of a compound will decrease, again a decrease in the partition coefficient represents an increase in its headspace (gas phase) concentration. In headspace the samples are heated and allowed to thermally equilibrate before sampling, to reach the maximum concentration of analytes in the gaseous phase.

The partition coefficient (K) can also be affected by the addition of salt to water samples. The salt is added directly to the headspace vial; the oven of the HS-trap can be fitted with an optional

shaker that will aid in diffusion of the salt in the sample matrix. The salt will act to decrease the partition coefficient of more polar compounds, further improving the quantitation limits. In this analysis many of the compounds are polar, and salting is a viable technique to improve recovery, however the data presented here does not utilize salting.

In classical headspace a small portion of the headspace is injected into the analytical column; the GC column has a limited flow rate, too long a sampling time will cause peak broadening and poor resolution. As a result, only a small percentage of the headspace volume can be sampled, in 8260 this is further limited by the gas flow into the mass spectrometer. Since a small percentage of the sample is injected a large dilution is unavoidable. The headspace trap technique eliminates this dilution; the entire headspace is passed across a cool thermal desorbtion trap. Allowing the collection of the entire sample; the maximum amount of the analytes of interest are collected and transferred to the column without overloading the carrier gas.

The elimination of the dilution effect can be pushed one step further with multiple headspace extractions. The vial can be repressurized, allowed to equilibrate, and the headspace collected, up to three more times. This acts as a concentration step improving detection limits one step further. The multiple headspace extraction technique was not necessary in the analysis presented here.

Once the headspace is collected on the adsorbent trap, the trap goes through dry purge with carrier gas to remove any residual moisture. Following sample collection and dry purge the trap is ballistically heated to desorb the analytes through the heated transfer line and into a tight band on the head of the analytical column. During the sample collection process, a column isolation flow keeps a constant flow down the column and into the mass spectrometer. The column isolation flow can also be utilized to keep the GCMS system free from air while maintenance procedures are performed on the headspace system.

Instrument Conditions

The instrumentation used in the technique was a PerkinElmer Clarus[™] 500 GC/MS system is configured with a PerkinElmer TurboMatrix[™] Headspace 110 Trap. The instrumental conditions are summarized in Table 1.

HS-Trap Con	ditions	GCI	IS Conditions
Needle	90 °C	GC	PerkinElmer Clarus® 500
Transfer Line	120 °C	Oven Program	Initial Temperature: 40 °C
Vial Oven	80 °C		Hold 0.0 minutes
Trap Low	40 °C		Ramp 1: at 10 °C/min to 100 °C
Trap High	280 °C		Hold for 0.0 minutes

Table 1: Instrument Conditions Used for (Volatile) 8260 Analysis Presented in the Paper

QA/QC Protocol

The analysis presented here was carried out following the QA/QC protocol of 8260. Method 8260 mandates that QA samples be analyzed on a GCMS system every 12 hours (called a "clock"). When the data presented here was collected each clock was initiated with a blank and BFB (Bromoflurorbenzene) injection, to verify the system integrity and mass spectrometer tuning. The BFB check is a background subtracted average of the three scans across the apex of the peak which is compared to EPA-specified ion ratio.

Method 8260 calls for a minimum of five calibration levels in the initial calibration. The calibration used in this application uses 6-8 points across a wider than average calibration range. A wide calibration range was chosen to allow laboratories to reach lower quantitation (reporting) limits, while still bracketing higher level samples, without dilution. Most compounds were calibrated from $0.5 \mu g/L$ to $200 \mu g/L$, with TBA and 1,4 Dioxane at a decreased range (see Table 2).

To prepare analytical standards an intermediate stock solution was created in methanol; this was diluted in water to the final concentration of each curve point. The standards were added to 22mL headspace vials, with surrogates, and internal standards. In the case of the curves presented in table 1, no special techniques were employed, such as salting or multiple headspace extractions, to aid in recovery.

Calibration Compound	Low Standard Concentration	High Standard Concentration	%RSD
MTBE	0.5 µg/L	200 µg/L	10.80
TBA	10 µg/L	1000 µg/L	8.97
Diisopropyl Ether	0.5 μg/L	200 μg/L	7.67
ETBE	0.5 µg/L	200 µg/L	4.88
1,4-Dioxane	10 µg/L	150 µg/L	10.27
TAME	$0.5 \ \mu g/L$	200 µg/L	6.12

Table 2: Concentration Range and Percent Relative Standard Deviation for an Example List of Fuel Oxygenates via 8260

After calibration, the precision of the system was tested 5 duplicate standards were prepared, each was sampled twice to give 10 replicate analytical runs. The precision test standards were prepared in a similar fashion to the initial calibration standards. Internal standards and surrogates were added with a gas tight syringe by hand to each vial. The average concentration of the 10 duplicate injections was calculated and the percent relative standard deviation calculated. The percent relative standard deviation for all of the fuel oxygenates in this analysis was well below 10% (see table 3). This data shows that the sample introduction is very precise and reproducible.

	% RSD
Compound	(over 10 injections)
methyl tert butyl ether	5.03%
tert butyl alcohol	4.01%
Isopropyl ether	4.60%
ethyl tert butyl ether	4.01%
1,4-dioxane	6.66%
tert amyl methyl ether	4.49%

Table 3: The Percent RSD of Relative Concentration over 10 Injections

DISCUSSION

The combination of two commonly used analytical techniques, static headspace and thermal desorbtion, has provided an analytical method well suited for low level analysis of low molecular weight alcohols, ketones, ethers in environmental matrices. The increasing interest surrounding the environmental analysis of fuel oxygenates has created a need for the analysis of this class of compounds. Without modifying instrumental parameters optimized for a full 8260 analysis, we have shown it possibly to include a full list of fuel oxygenates using the technique presented here.

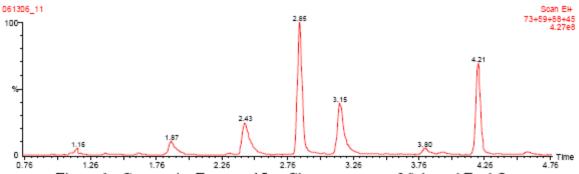

Figure 1: Composite Extracted Ion Chromatogram of Selected Fuel Oxygenates The scale of chromatogram is skewed by the strong responding DIPE and 1,4-difluorobenzene an internal standard (4.21 min.). MTBE (2.43 min), DIPE (2.85 min), (ETBE 3.15 min).

The QA/QC criteria of 8260 have been adhered to, the integrated HS-Trap, GSMS system continuously meets the ion ratio criteria for BFB mandated by 8260. An initial calibration curve with 5 points or more shows excellent percent relative standard deviations across a wider than average calibration range.

CONCLUSION

Many states are requiring that laboratories include additional compounds in their 8260 list; very often these compounds are low molecular weight alcohols, ketones, and ethers. Typically laboratories are challenged to meet detection limits and QA/QC requirements on this extended list. Presented here is a simple method to provide an option for laboratories. The technology of the HS-Trap allows it to excel in the analysis of this class of compounds, as a result of a heated

headspace and the ability to sample the entire headspace on an adsorbent trap. Thus meeting the low detection limits imposed by many states and the QA/QC criteria mandated by 8260.

This technique provides the simplicity of headspace sample preparation, with an extremely low risk of cross contamination and sample matrix interference. Additionally, salting and multiple headspace extraction may provide the laboratory options for improved sensitivity if need be.

PerkinElmer

PerkinElmer

Use of Low Molecular Weight Alcohols, Ketones, and Ethers

- > The oxygenated fuel burns more completely in automobile engines, reducing tailpipe emissions
- The Clean Air Act of 1990 required the addition of oxygenated compounds to gasoline.
- > The most commonly used fuel oxygenate additive is methyl tertiary butyl ether (MTBE).
- СН₃ | СН₃ С О С | СЧ Other oxygenates include:
 - Tert-Amyl-Methyl Ether
 - Ethyl-Tert-Butyl Ether
 - Tert-Butyl Alcohol
 - Ethanol

Environmental Risks Associated with Fuel Oxygenates

- > The transportation, transfer, and storage of oxygenated fuel in underground tanks presents a opportunity for release into the environment.
- > A result of their more polar nature, fuel oxygenates are easily miscible and/or soluble in water.
- Thus leaks and spillage will contaminate ground, surface, and waste waters. The polarity will create waste plumes which spread rapidly and are difficult to control and remediate.
- Additionally many are believed to pose a potential threat to human health.

- Many states have regulations controlling acceptable levels of fuel oxygenates in ground, surface and waste water.
- > MTBE is being phased out as a fuel oxygenate.
- Consequently, there is an increasing need for the analysis of fuel oxygenates in water.
- This technique describes the use of headspace with trap GC/MS for low level determination of fuel oxygenates by EPA Method 8260.
- This technique will provide a simple, robust, and reliable method to quantify a full list of VOCs, including an expanded list of ethers and alcohols.

Trap Theory and Technology Summary

- > Governed by the equilibrium headspace principle
- Headspace focused onto an adsorbent trap, allowing the collection of the 'whole' headspace
- > Multiple cycle headspace extraction option
- > Trap dry-purge to remove moisture

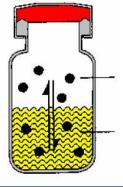

Equilibrium Headspace Principle

- > Equilibration must be met.
- Must consider matrix (partition coefficient is matrix dependent)
- Sample must represent a partitioned system

 $K = C'/C^g$

- K = Partition coefficient of a volatile
- Cl = Concentration in the liquid phase
- Cg = Concentration in the gas phase

- Options for analyzing difficult components at low levels

Variables in Lipids Analyses and Affect on Data Quality

Craig Hutchings and Ann K. Bailey EcoChem, Inc.

ABSTRACT

The methodology for the determination of "percent lipids" in tissues is often not specified nor described in study protocols even though "percent lipids" results are commonly used to normalize contaminant data. Any errors or differences in the determination of percent lipids will be propagated throughout a study of biota-sediment accumulation factors (BSAF), undermining the quality or comparability of contaminant data. In many environmental laboratories "percent lipid" results are simply gravimetric determinations of the residue after solvent extraction of the tissue, and better labeled as total extractable organics (TEO). While laboratories evaluate the extraction efficiencies for contaminants, the extraction efficiency of lipids from tissue is many times not considered. However, lipids results can vary significantly depending on the method of extraction and the solvents used. Various methods for the determination of percent lipids (or TEO), and the use of reference materials (RM) to evaluate the uncertainty and comparability of lipids or TEO measurements will be discussed.

INTRODUCTION

The term lipid is used to describe a broad range of compounds that include fats, oils, waxes, sterols, and triglycerides and are used by organisms to store energy and in cell structures. Lipids exist within tissues in many forms, and the majority of organic contaminants are associated with two major forms referred to as the neutral pool and the membrane bound pool (l).

In environmental contaminant studies lipids are commonly used in assessing the bioaccumulation of organic compounds. The concentrations of contaminants in tissues are normalized to the percent lipids of the tissue and these normalized values are compared to sediment contaminant levels that have been normalized to total organic carbon (TOC) to develop biota/sediment accumulation factors (BSAF). These BSAF may be used in modeling the impact of contaminated sediments on organisms coming in contact with the sediment. One example is the use of BSAF in assessing the suitability of disposal of dredged sediments in deep water areas (2, 3). Lipid content is also frequently used in the food web modeling studies assessing the transfer of contaminants from one trophic level to another (4).

Many times little attention is paid to the analytical methodology used for determining lipids. Study protocols and academic papers frequently specify in detail the methods used for the determination of the contaminants, the technique used to determine percent lipids is rarely specified. Furthermore, no standard method for lipids, determination exists leaving laboratories with little guidance. Various studies (5, 6) have found that the use of different extraction solvents and methods will deliver different results for lipids and these differences can have significant affects on the comparability and usefulness of the data.

DISCUSSION

There are two common types of analytical errors that can apply to the analysis of lipids: 1) analytical bias, which can cause problems with comparability to other data sets; and 2) inconsistent application of methodology causing imprecise results. Analytical bias can be caused by the use of differing extraction solvents, extraction equipment, and/or methods which are inappropriate for the matrix. Inaccurate or imprecise lipids data can be caused by improper application of the extraction equipment or improper laboratory techniques.

Analytical Bias

The lipids pools described above each have different extraction requirements. The neutral pool is best extracted using non-polar or semi-polar solvents while the membrane bound pool requires a mixture of polar and non-polar solvents (l). Several factors influence with pool environmental contaminants are associated with including chemical structure, the species, the tissue type, such as muscle, viscera, skin, etc. The association to these pools can also vary by season and physical and chemical stresses on the organism can also affect the association (5).

Lipids concentrations are usually determined by extracting the tissue with one or more solvents and allowing this extract to evaporate at room temperature. The weight of any residue remaining after evaporation is divided by the weight of the tissue extracted and expressed as percent lipids. The value determined by this technique is better described as total extractable organics (TEO) as it is strictly gravimetric as no distinction is made between lipids or any other residue remaining after evaporation. This gravimetric determination is usually performed on a portion of the extract that is used for the contaminant analysis. And while laboratories can go to great lengths to optimize and validate their procedures for the recovery of contaminants through the use of spiked matrices and reference materials, it is not common, nor always practical, to do so for TEO.

In the absence of a standard method it is commonly suggested that whatever technique is used for the determination of lipids be compared to the Bligh Dyer method (5, 7) by performing separate analyses on a subset of the samples. However, due to limitations in sample size and additional costs this comparison is not often performed. The U.S. Environmental Protection Agency (8) recommends methylene chloride as extraction solvent for all lipid analyses, however under USEPA prescribed or performance based methods laboratories may use a wide variety of extraction techniques and solvents for the contaminant analysis. These extraction techniques and solvents are summarized in Table 1.

Not all of the listed extraction techniques and solvents in Table 1 are equally efficient at extracting all types of lipids Studies (5, 9) have found differences of up to three fold resulting from the use of different extraction solvents. As far as extraction techniques, studies (6, 10) have indicated that soxhlet does not always yield complete lipid extraction. Validation of a method focusing only on chemical pollutants may miss potential problems in extracting lipids.

Other factors affecting lipid results are sample size (11), the type of species and the tissue type being analyzed (5, 8). As mentioned above, Randall (5) has shown that at different times contaminants may be associated with one lipid pool at one time but this association can change based on where the organism is in its reproductive cycle, the time of year, and any stresses placed on the organism. These variations make it exceedingly difficult to adequately evaluate an extraction method for what may have worked initially may not be applicable to other species or other seasons.

As an example of analytical bias, a data set of total DDT (defined as the sum of 2,4'-DDD, 4,4'-DDD, 2,4'-DDE, 4,4'-DDE. 2,4'-DDT and 4,4'-DDT) and total PCB homologues results from the analysis of a fish tissue of a single species is provided in Table 2, and the lipid corrected data is provided in Table 3. These tables provide example contaminant and lipid results for the same set of fish fillet samples from an initial analysis and subsequent re-analysis. The initial set of results was obtained after the laboratory's standard extraction methodology, based on EPA Method 8270C (12) and applied to DDTs and PCB congeners. The second data set was reported after refining the extraction procedures. While the results that have not been lipid corrected are relatively similar for the two data sets (Figures 1a and 1b), the lipid corrected results have much greater differences (Figures 1c and 1d). Figure 2 illustrates the differences between the lipid results (as TEO) before and after method refinement.

Imprecise Results

Because lipids analysis is simply a gravimetric technique, many times the importance of implementing careful and consistent techniques is not considered as critical as the more complex aspects of analytical methodologies. Thus, the more experienced analyst usually will be found performing the instrumental analysis involving, for example, mass spectrometry, while the "simple" measuring and weighing process for lipids is assigned to a less experienced analyst. However, this gravimetric measurement can involve as little as 100 microliters of solvent, and the weighing of residues as little as 1 milligram.

Care must be taken that the solvent measurement process is accurate and consistently performed. Potential sources of error can be:

- Syringe not calibrated,
- Inconsistent reading of sample volume,
- Inconsistent delivery of sample volume.

When measuring such small quantities consistent technique is critical. Even a change in humidity or minor drift of the balance can significantly affect the results.

For most analytical methods, quality control is assessed on a batch by batch basis by the analysis of a spike or blank spike for accuracy; and a duplicate or matrix spike duplicate for precision. Because lipids are a multi-component determination, the mixing and spiking of representative material is not readily performed. Thus matrix spikes (MS) are not usually performed for lipids. Also, the accuracy of lipids results in blank spikes or laboratory control samples (LCS) many times are not assessed, rather the focus of the quality control checks is for the contaminants of concern. So, unless a reference or control material with a known concentration of lipid is specified as a quality control check there may be no method for independent assessment of accuracy.

As far as an assessment for precision, duplicate analysis usually provides only a measure of precision for one sample every batch. If only a few samples or batches are analyzed, poor

precision may be documented, but from the analysis of only a few samples it is difficult to assess the significance of poor replication. Thus, standard quality control checks many times do not provide enough information to assess the accuracy and precision of lipid analysis. A reference or control material similar in matrix to samples being analyzed can be most useful in determining the quality of the lipid results (*13*).

Figure 3 is a summary of the lipid results for NIST SRM1946, Lake Superior Fish Tissue, which accompanied the analysis of 37 batches of fish fillet samples. The data used in the examples above are from this dataset. For these batches the LCS, MS, and laboratory duplicate data was generally very good indicating adequate accuracy and precision for the contaminant data. The contaminant data from the reference material was also generally very good. However, the results from the reference material lipids analysis were not as good. The initial analysis data was seemingly random, being both inaccurate and imprecise. Based on this observation the laboratory performed further method development and subsequently performed re-analysis.

CONCLUSION

While it is common for quality assurance project plans (QAPP) and other project set up documents to specify in great detail how samples are to be collected and analyzed for the primary target analytes, rarely is the method for the determination of lipids specified. However, there can be much variability in lipids values depending on how the value is determined. A 3 to 5 fold variation in lipids values can mask patterns that may be present in the contaminant data, or mis-identify correlations.

Because lipid results are used many times to normalize contaminant data from tissue analysis, it is important that quality control of the test method be more consistently performed. This can be improved by: 1) A standard method for lipids, or TEO, should be agreed upon and clearly specified during project planning that involves tissue analyses. Extraction procedures and solvents should be specified and methods clearly described in the laboratory Standard Operating Procedures (SOPs). As for any other performance-based methodology, the lipid analysis should be validated using a reference tissue similar in matrix to the tissue of interest. 2) An analysis of a control or reference materials for lipids should be incorporated into the quality control samples with each analytical batch. The analysis of a laboratory duplicate alone cannot provide enough information regarding overall precision and accuracy.

Quantitative Defense of Extract Dilution for Hydrocarbon Interferences in Semi-Volatile Organic Analysis by GC/MS

Mark Bruce Ph.D., Marcel Mol, Tom Hula

Severn Trent Laboratories, Inc., North Canton, OH

ABSTRACT

Hydrocarbon mixtures are common and significant interferences when determining semi-volatile organic analytes by GC-MS in extracts of environmental soil samples. When the hydrocarbon content of the sample extract is high, the ability to detect and quantify target analytes is degraded. Varying amounts of diesel fuel and motor oil were added to a calibration standard at the quantitation limit. As the hydrocarbon content increased, a low bias was observed for analytes such as benzyl alcohol, benzidine and 2,4-dichlorophenol. Of greater concern were the analytes that were not detected when the hydrocarbon content was high. A few of the "disappearing" analytes were nitrobenzene, pyridine, 4-nitrophenol, and pentachlorophenol. In those instances, the non-detect result was a false negative.

Determining the relationship between hydrocarbon content and the frequency of false negatives can guide the analyst toward making the proper extract dilution. This challenging balance point weighs sensitivity and low quantitation limits vs. data accuracy and avoidance of false negatives. For example, diesel fuel concentrations up to 5.9 mg/kg did not affect the quantitation of nitrobenzene at 33 ug/kg. Once the diesel fuel concentration reached 11.7 mg/kg, nitrobenzene was non-detect.

INTRODUCTION

Push for Lower Reporting Limits

Low concentration risk assessment goals such as the EPA Region 9 Preliminary Remediation Goals, are fueling the drive for analysis of environmental samples at lower and lower analyte concentrations. Hydrocarbon impacted sites must be demonstrated to have key hazardous constituents below certain decision thresholds in order to establish that certain costly remediation steps are not necessary. Newer gas chromatography - mass spectrometry instrumentation has improved environmental monitoring sensitivity, however interference problems from hydrocarbons remain.

Elevated reporting limits (RLs) usually occur when the sample components necessitate dilution of the sample extract to maintain the integrity of the analytical process and instrumentation. Occasionally this produces non-detect results at RLs that are higher than the action limit or decision threshold. Thus, the environmental data user is not able to demonstrate that particular hazardous contaminants are below a predetermined action limit. This situation can lead to additional environmental cleanup or property usage restrictions that might not be necessary and are usually expensive.

Reasons to Dilute

There are several reasons that a laboratory might dilute a sample or sample extract prior to analysis. If an appropriate dilution is not performed, data quality can be compromised for the sample of interest. In some instances data quality of subsequent samples in the analytical process can also be compromised. The most common reasons for dilution of environmental water and soil samples or their extracts are to prevent calibration range exceedance, carryover of analyte or non-analyte components into subsequent analyses, damage to the analytical system and chromatographic or mass spectral interference or overload.

This last dilution cause is the focus of this paper. High concentrations of non-analyte components can overload either the chromatograph or mass spec detector. Non-analyte components can mask the presence of target analytes by adding to the chromatographic and spectral background, making it impossible to definitively identify analytes using standard chromatographic data systems commonly employed for US EPA methodologies. In extreme overload conditions, retention time shifts and distorted mass spectra occur. Unfortunately for multi-analyte methods covering many different types of functional groups such as US EPA Method 8270, there are no universal cleanup methods that remove hydrocarbon interferences without reducing analyte recovery as well.

EXPERIMENTAL DESIGN AND PROCESS

Focus on GC/MS Overload Scenario

This paper will focus on dilutions caused by moderate GC/MS (Method 8270 semivolatile organics) overload conditions produced by diesel fuel and motor oil. Identifying analytes becomes increasingly difficult as the concentration of hydrocarbons on-column increases. Interferences occur both in the selected ion chromatograms and mass spectra. Eventually the interfering component concentrations become too high to positively identify certain target analytes. Sample extract dilutions are then needed to reduce the background interference to a tolerable level in order to maintain defensibility of non-detect results. Inadequate dilutions will lead to false negative results because high concentrations of hydrocarbons in the sample extract obscure the presence of low concentration target analytes.

Design

Target analyte standards (0.25, 0.5 and 1.0 ng on-column) containing the most frequently requested semi-volatile organic analytes were prepared at concentrations corresponding to the normal reporting limits (RL) in soil samples (33, 67 and 133 ug/kg). Five different concentrations (22, 44, 88, 176 and 352 mg/L in the extract) of diesel fuel or motor oil were added to these RL standards. These hydrocarbon concentrations would correspond to 1.5, 2.9, 5.9, 11.7 and 23.5 mg/kg in a contaminated soil sample. All hydrocarbon spiked standards were analyzed sequentially. The GC/MS chromatograms were evaluated using a standard Target (Thermo) chromatography data system.

Analytical Sequence

The analytical sequence is summarized in Table 1. The spiked RL standards with the lowest hydrocarbon concentrations were analyzed first, followed by subsequent standards with increasing hydrocarbon concentration. A mid-level continuing calibration standard was analyzed

between each diesel fuel and motor oil spiked standard to assess the condition of the GC/MS system.

Table 1: Analysis Sequence

Cal. 6 Diesel 4 - 250x diesel fuel + 0.25 ng OC std Cont. Cal. 7 Motor 4 - 250x motor oil + 0.25 ng OC std Cont. Cal. 8 Diesel 5 - 125x diesel fuel + 0.25 ng OC std Cont. Cal. 9 Motor 5 - 125x motor oil + 0.25 ng OC std Cont. Cal. 10

Equipment and Method

Method 8270 analysis was performed using an Agilent 6890/5973 inert source GC/MS system equipped with Agilent injection port liner and column (DB-5.625 20m X 0.18 mm ID). The temperature program was: 60°C for 1 min., ramp at 35°C /min to 320°C and hold for 2 min.

GENERAL RESULTS

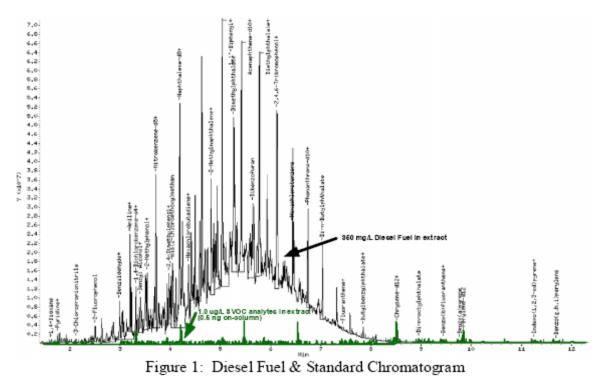

The analyte results fell into four different categories: no effect, high bias, low bias or false negative. The majority of the semivolatile organic analytes were not affected by the hydrocarbons within the concentration range studied. Several polyaromatic hydrocarbon analytes (PAHs) were in the diesel fuel and showed high biased results. This was not an indication of interference, but did eliminate these analytes from further study. Some analytes exhibited a decrease in response as the concentration of hydrocarbons was increased, thus producing a low biased result. Other analytes produced false negative results as the hydrocarbon concentration increased. These analytes were known to be present in the RL standard but could not be identified in the chromatogram because of interference from the hydrocarbon mixtures. These false negative responses would produce non-detect results that cannot be defended. Thus, extract dilution with corresponding elevation of the reporting limit would be necessary.

The repeatability of the continuing calibration standards (average 4% RSD) interspersed throughout the sequence demonstrate that the conditions of the GC system did not degrade

during the course of the experiment. The lack of permanent damage to the GC is not surprising since hydrocarbons are generally unreactive under the GC conditions of Method 8270.

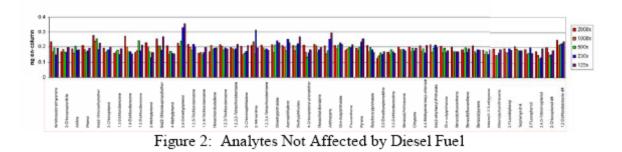

DIESEL FUEL RESULTS

The chromatogram of the highest concentration diesel fuel analysis was overlaid with that of the RL standard to show the magnitude of the concentration differences between the target analytes and the interfering hydrocarbon mix (Figure 1).

Non-affected Analytes

Most of the analyte responses were not affected by the increasing diesel fuel concentration within the range studied. These are shown in Figure 2. Note the consistency of the analyte response despite the increasing hydrocarbon concentrations or sample extract dilution factors. This is a demonstration of the effectiveness of modern GC/MS systems to minimize the effects of potentially interfering hydrocarbon mixtures.

Diesel Component Analytes

Several of the analytes were also components in the diesel fuel. Thus, the extract concentration and on-column amount of these PAHs and other semi-volatile organic analytes increased as the concentration of diesel fuel increased. This produced a high biased result for these analytes, but was not indicative of any method shortcomings. The effect of increasing diesel fuel concentration could not be studied for these analytes shown in Figure 3.

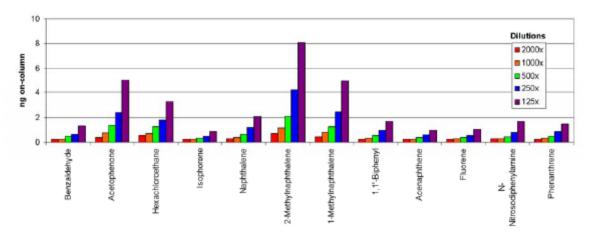

Figure 3: Diesel Fuel Component Analytes

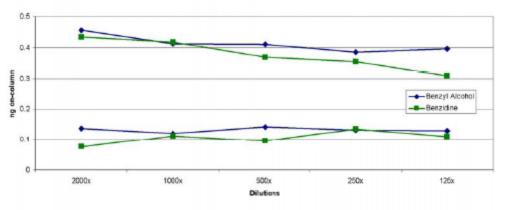

Figure 4: Analytes Biased Low by Diesel Fuel

Low Biased Analytes

A few analytes showed decreasing response (Figure 4) as the effective dilution was decreased, thereby increasing the final extract concentration of diesel fuel. In other words, increasing the diesel fuel concentration decreased the response from these analytes producing a low biased result.

False Negative Analytes

The false negative results were the most alarming response to increasing diesel fuel interference At high dilutions (low diesel fuel concentration) these analytes were detected and accurately quantified. However, as the diesel fuel concentration increased, these analytes were not detected even though they were known to be present. The hydrocarbon background had increased to the point of obscuring the chromatographic peaks and mass spectra of these analytes. This false negative result (non-detect) at the associated reporting limit produced data that understated actual target analyte concentration. This could compromise the accuracy of a risk assessment or other decisions based on the result of this under-diluted sample. Figure 5 shows the increasing frequency of false negative responses for these analytes as dilution decreases and diesel concentration increases.

The increasing diesel fuel interference effect is shown in Figures 6 and 7 for nitrobenzene. As the hydrocarbon background increases in the ion chromatograms and mass spectra, interference precluded detection of the analyte. Figure 6 shows the disappearance of the three major ions amongst the co-eluting hydrocarbons. Figure 7 shows hydrocarbon spectra over running the nitrobenzene spectrum.

MOTOR OIL RESULTS

The chromatogram of the highest concentration motor oil analysis was overlaid with that of the RL standard to show the magnitude of the concentration differences between the target analytes and the interfering hydrocarbon mix. This is shown in Figure 8.

Non-affected Analytes

Most of the analyte responses were not affected by the increasing motor oil concentration within the range studied. These are shown in Figure 9. Note the consistency of the analyte response despite the increasing hydrocarbon concentrations or sample extract dilution factors. This is a demonstration of the effectiveness of modern GC/MS systems to minimize the effects of potentially interfering hydrocarbon mixtures.

Motor Oil Component Analytes

There were no analytes that appeared to be a component in the motor oil.

Low Biased Analytes

A few analytes showed decreasing response (Figure 10) as the effective dilution was decreased, thereby increasing the final extract concentration of motor oil. In other words, increasing the motor oil concentration decreased the response from these analytes producing a low biased result.

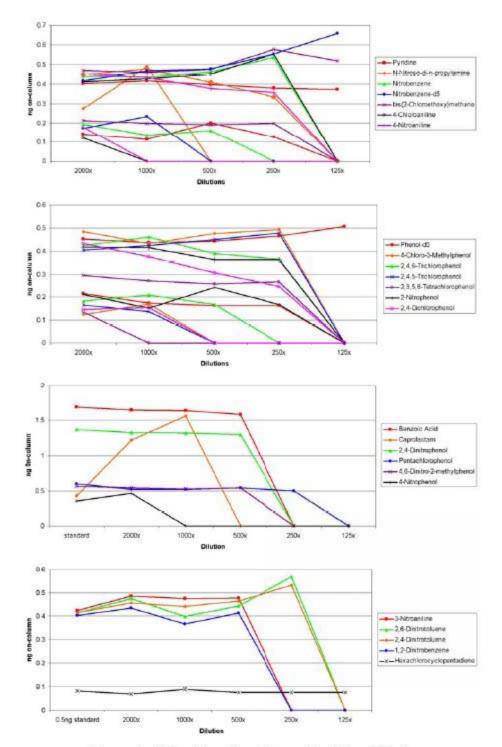

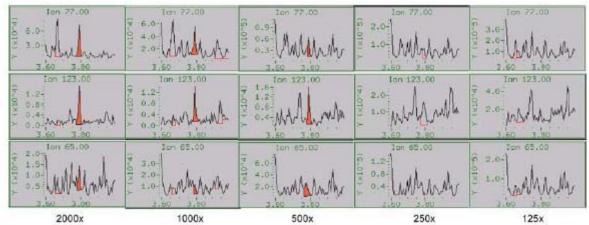

Figure 5: False Negatives Caused by Diesel Fuel

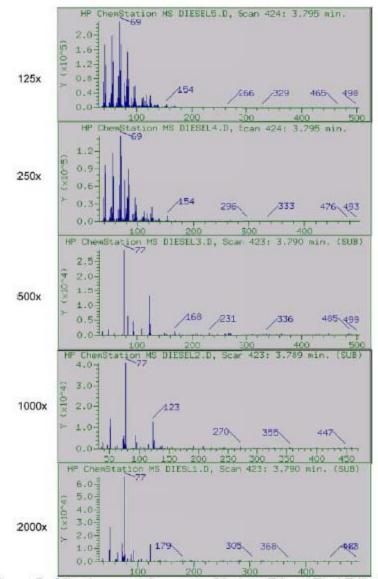

Figure 7: Nitrobenzene Spectra at Various Diesel Fuel Dilutions

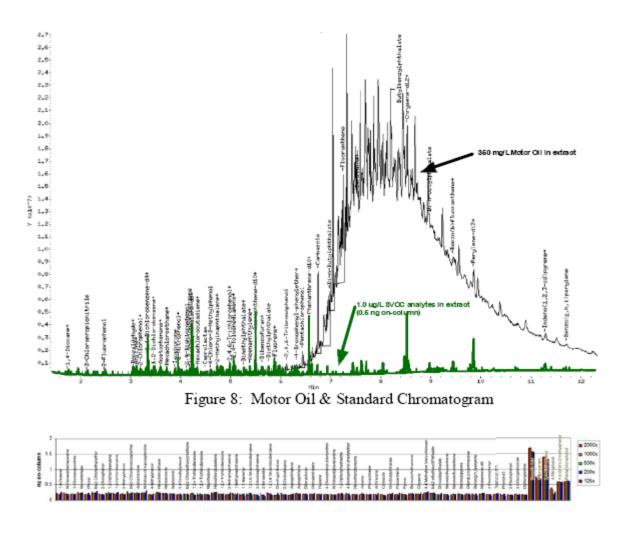

Figure 9: Analytes Not Affected by Motor Oil

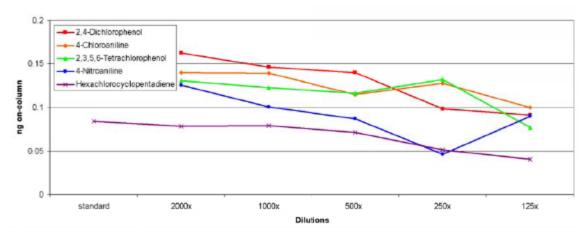

Figure 10: Analytes Biased Low by Motor Oil

False Negative Analytes

False negative responses were also found for high concentration motor oil samples. At high dilutions (low motor oil concentration) these analytes were detected and accurately quantified. However, as the motor oil concentration increased, these analytes were not detected, even though they were known to be present. The hydrocarbon background had increased to the point of obscuring the chromatographic peaks and mass spectra of these analytes. Similar to the diesel fuel results, this false negative result (non-detect) at the associated reporting limit produced data that understated actual target analyte concentration. This could compromise the accuracy of a risk assessment or other decisions based on the result of this under-diluted sample. Figure 11 shows the increasing frequency of false negative responses for two analytes as dilution decreases and diesel concentration increases.

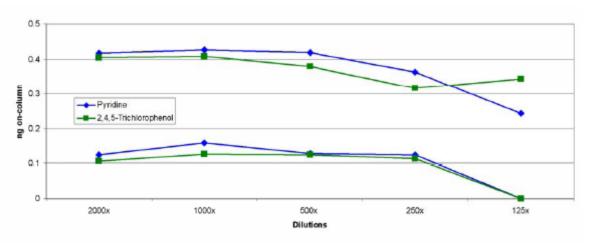

Figure 11: False Negatives Caused by Motor Oil

CONCLUSION

Hydrocarbon mixtures are common and significant interferences when determining semi-volatile organic analytes by GC-MS in extracts of environmental soil samples. When the hydrocarbon content of the sample extract is high, the ability to detect and quantify target analytes is degraded.

Inadequate dilution to mitigate diesel fuel and motor oil interferences causes false negative and low bias results for 22 semivolatile organic analytes when analyzing by EPA Method 8270. In particular, the non-detect results for these analytes from under diluted sample extracts do not demonstrate the absence of the analyte at the normally calculated reporting limit. Dilution or other means of estimating an appropriate elevated reporting limit are necessary. The push to lower reporting limits in order to meet risk based criteria in hydrocarbon contaminated samples should not compromise the defensibility of those analyte reporting limits by potentially masking the presence of the analytes of interest.

Quantitative Defense of Extract Dilution for Hydrocarbon Interferences in Semi-volatile Organic Analysis by GC/MS

Abstract

 Hydrocarbon interferences can cause false negative results

- Semivolatile Organic Compounds
- Method 8270 GC/MS
- Usually soils or other contaminated solids

• Example - Nitrobenzene: 33 ug/kg

- Diesel fuel
 - 5.9 mg/kg dilution OK, analyte found
 - 11.7 mg/kg not enough dilution, false non-detect

Leaders in Environmental Testing

Push for Lower Reporting Limits

- Low concentration risk assessment goals
 - EPA Region 9 Preliminary Remediation Goals
- Hydrocarbon impacted sites
- GC/MS sensitivity improved
- Some interferences remain

SEVERN TRENT STL

Leaders in Environmental Testing

Elevated reporting limits

- Sample components >> dilution
- Avoid "damage" to analytical data or instrumentation
- Occasionally RLs > action limit
- Not able to prove < action limit

Reasons to Dilute

- Calibration range exceedance
- Carryover of analyte or non-analyte components into subsequent analyses
- Damage to the analytical system
- Chromatographic or mass spectral interference or overload

SEVERN STL

Leaders in Environmental Testing

High concentrations of non-analyte components

- Overload GC or MS
- Mask the presence of target analytes
 - Chromatographic and spectral background
- Extreme overload conditions
 - Retention time shifts
 - Distorted mass spectra occur
- No good cleanup methods that remove hydrocarbon interferences

Focus on GC/MS Overload Scenario

- Method 8270 semivolatile organics
- Diesel fuel & motor oil
- Interferences occur
 - In selected ion chromatograms
 - In mass spectra
 - Too high to identify target analytes

Dilutions reduce interference

Defensible non-detect result

• Inadequate dilutions > false negatives

CONCURRENT SESSIONS

Chemical Speciation – Cr (VI) Species

A NEW TOOL TO ASSURE THE ACCURACY OF CR(VI) MEASUREMENTS

Buckley, Dr. Brian – Rutgers University Environmental Occupational Health Sciences Institute; Long, Dr. Stephen – United States Department of Commerce National Institute for Standards and Technology Analytical Chemistry Division; MacDonald, Bruce – NIST Measurement Services Division; Nagourney, Stuart J. – New Jersey Department of Environmental Protection Office of Quality Assurance; Werner, Rachel – NJDEP OQA; Yang, Shen-Yi – United States Environmental Protection Agency Office of Solid Waste

The accuracy of analysis of speciated metals in non-aqueous matrices has been a dilemma for the scientific and regulatory communities for many years. For example, most soil samples analyzed for Cr(VI) by EPA Methods 7196A (alkaline extraction) and 7196A (colorimetry) for the New Jersey Department of Environmental Protection fail method-required QA because of matrix-induced interferences. Use of EPA Method 6800 (speciated isotope dilution mass spectrometry) offers a tool to diagnose problems and provide reliable Cr(VI) data; however, to date only one laboratory is certified by the NJDEP to perform this test method. While Department recommendations state that Method 6800 is to be used when definitive Cr(VI) information is needed (for example, when a "No Further Action" decision is rendered at a remedial site), the majority of future Cr(VI) tests may continue to be performed by other analytical methods. What do we do to assess the quality of those data?

To address this concern, a collaborative effort involving NJDEP, NIST, USEPA, and EOHSI is underway to produce a Standard Reference Material (SRM) for Cr(VI) using source material from sites contaminated with this material in Hudson County, New Jersey. This will be the first attempt by NIST to produce a speciated chromium SRM from a natural source. A description of the sampling, sample preparation, stability testing and analysis plans will be presented.

A NEW TOOL TO ASSURE THE ACCURACY OF Cr(VI) ANALYSES

Stuart J. Nagourney, Research Scientist NJ Department of Environmental Protection Office of Quality Assurance

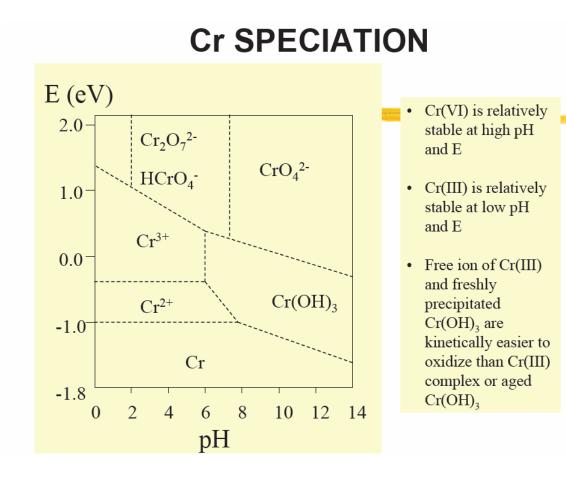

stu.nagourney@dep.state.nj.us 609-292-4945

Cr SPECIATION

rightarrow Toxic and much more mobile ightarrow (CrO₄)⁻, (Cr₂O₇)⁻²

NJ Cr(VI) CONTAMINATED SITES

ANALYSIS OF Cr(VI)

∺Air: sample collection issues
 NIOSH 425
 OSHA 215

₩ Waters: little or no sample preparation
Colorimetric: 3500
IC: 218.6

#Soils: Much more complicated

ANALYSIS OF Cr(VI) IN SOILS

₭Two steps needed:
Extraction
Determination

EXTRACTION OF Cr(VI) IN SOILS: METHOD 3060A

Take 2.5 g soil sample in 50 ml. of basic extraction solution (0.28 M Na₂CO₃/0.5 M NaOH)
Cover, stir, and heat at 90-95°C for 60 min.
Filter solution through 0.45 mm membrane filter
Neutralize the extract by slowly adding HNO₃

₿ Adjust to pH of 7.5

#Transfer and dilute to 100 ml.

XNow you are ready for analysis

Cr(VI) IN SOIL: DETERMINATIVE OPTIONS

₩Method 7196A - UV-Vis

₩Method 7199 - IC w/UV-Vis

∺Method 6800 - Speciated ICP-MS

Cr(VI) IN SOIL: NJ ANALYTICAL CHRONOLOGY

- 1980's" SW846 includes Method 3060 (hot alkaline digestion) and colorimetric determination (Method 7196A)
- △1992: Many problems (mostly low spike recoveries) cause EPA to withdraw Method 3060; <u>a 1st and only!</u>
- Some states, including NJ, come up with their own alkaline extraction methods
- □ 1994: EPA approves Method 7199 (IC)
- ☑ 1995: Industry-sponsored research provides data for an alternate alkaline extraction method, brought to EPA
- 1996: EPA approves as 3060A, but with additional QA
- △ 1996 2005: NJ continues to use its own ext. method
- △1998: EPA approves Method 6800 (SIDMS)

METHOD 3060A CONCERNS

Extraction must be quantitative and selective, without causing:

Oxidation of Cr(III) to Cr(VI) and/or

☑Reduction of Cr(VI) to Cr(III)

∺Known problems include:

- During extraction, some metals promote oxidation (Mn); others can cause reduction (Fe)
- Organics, sulfides and others promote reduction
- What about the method of detection??

DETERMINATIVE METHOD CONCERNS

Boes Method 7196A induce errors? Yes!

#Does Method 7199 induce errors? ????

#Are biases high or low? **Yes! and Yes!**

#Any reliable QA tools? Not Yet

₩What about Method 6800??

SOME OF THE CHEMISTRY PROBLEMS

Method 3060A does not automatically reject data that fails method QC

#>70% of soils tested in NJ fail Method 3060A QC; what to do w/data w/0% spike recoveries?

How do you know that your sample behaves like the sample in the batch that was spiked?

How do you develop a reliable QA program?

BIGGER PICTURE ISSUES w/CR(VI) IN NJ

Lots of sites still to be cleaned up; clean-up costs in \$billions; real-estate potential much greater

#Environmental justice concerns

RPs have done almost all current Cr(VI) research

#Press and local political action committees are now heavily involved

WHAT'S GOING ON NOW IN NJ?

Huntil late '03, all data by 3060/7196A: > 70% fails QA. Many sites issued NFAs based upon data that fails QA

#12/03: Judge ruled NJDEP was not being protective enough; questioned analytical methods used to close sites

3/04: NJDEP Cr(VI) Workgroup formed

#2/06: Workgroup Report finalized

NJDEP Cr WORKGROUP RECOMMENDATIONS I

- OQA will add USEPA Method 6800 to its list of certifiable analytical methods.
- Method 3060A will be used for digestion of all future soil samples for Cr(VI) analysis.
- A tiered approach to selection of determinative methods for Cr(VI) will be used
- Total chromium will be analyzed concurrently with Cr(VI) for all samples.

NJDEP Cr WORKGROUP RECOMMENDATIONS II

- Method 6800 could be used when spike recoveries by other methods are < 75% or > 125%.
- The Department will develop a data usability policy for Cr(VI). Spike recoveries that do not meet method QA requirements will not be used for unconditional "No Further Action" decisions.
- Measurements of the oxidative/reductive (eH and pH) properties of the soil matrix will be made for all samples from sites with oxidizing or reducing conditions.

NJDEP Cr WORKGROUP RECOMMENDATIONS III

- Spike recoveries must meet the requirements stated in the analytical measurements for the Cr(VI) results to be acceptable without qualification.
- A Sample Delivery Group will consist only of samples of a similar matrix type.
- NJDEP will not re-visit old data
- The Department will arrange and participate in the development of speciated reference materials to be used when analyzing for Cr(VI) in non-aqueous sample matrices.

NJDEP Cr WORKGROUP RECOMMENDATIONS V

CR(VI) SRM PROJECT SUMMARY

• Project Team: NJDEP, NIST, EPA & Rutgers U.

- Source material collected at LSP
- Homogenization by USGS
- Stability of Cr(VI) in processed material to be studied 1st
- Interlaboratory comparison: 7196A, 7199 and 6800
- Evaluation of results

Cr(VI) SAMPLE COLLECTION at LIBERTY STATE PARK

Cr(VI) SAMPLE COLLECTION at LIBERTY STATE PARK

SOURCE MATERIAL HOMOGENIZATION BY USGS

#80 kg dried at RT for 3 days

1 kg. disaggregated to < 2 mm mesh size

50 kg. aliquots ball-milled for 16 hrs.

Blending in 10ft³ V-blender for 16 hrs.

- **#**UV-Irradiated using 2.5MRad Co-60 source
- Blended material (6.5 kg. batches) then spilt using custom 80 in. spinning riffler
- Bottled samples (80-100 g.) evaluated for correct mass range

Steve Wilson, USGS

STABILTY TESTING

- There is justifiable concern about the long-term stability of the processed material; this is a requirement for a SRM
- A selection across the lot of ~2500 bottles will be sent to labs. to be analyzed in triplicate over several months by:
 - 3060A/7196A
 - 3060A/7199
 - 3060A/6800
- Data will be reviewed by the Project Team before proceeding

INTERLABORATORY TESTING

- Once the stability of the processed material is assured, samples will be sent to ~35 laboratories worldwide that have volunteered to participate in an interlaboratory study
- Each laboratory will extract using 3060A, but analyze by their determinative method(s) of choice
- All data will be returned to the NJDEP who will organize and sort; results then sent to NIST for statistical analysis

AND THEN?

- If the data meets NIST's criteria for SRM issue, then the material will be commercially available sometime in 2007.
- NJDEP may require analysis of this SRM with all Sample Delivery groups for future Cr(VI) in soil measurements
- With commercial availability of Method 6800 and a reliable SRM, we will FINALLY be able to evaluate the efficacy of measurements of Cr(VI) in soils.

RECOVERY OF CHROMIUM SPECIES FROM SOILS; WHAT FACTORS ARE MOST IMPORTANT?

Buckley, Brian – Rutgers University Environmental and Occupational Health Sciences Institute; Lippincott, Lee – NJ Department of Environmental Protection; Murphy, Eileen – NJ Department of Environmental Protection; Nagourney, Stu – NJ Department of Environmental Protection; Johnson, Willie - Rutgers University Environmental and Occupational Health Sciences Institute; and Stiles, Robert - Rutgers University Environmental and Occupational Health Sciences Institute

Speciation of chromium is important because the chemical form of the metal means it is either a lung carcinogen or a micronutrient. At first glance, chromium speciation should be a relatively easy process. Both of the key species are stable under a wide variety of pH conditions. So why is this such a difficult assay? The answer lies in the extraction of the chromium from its matrices. Once the species are solublized, the redox chemistry of the chromium is governed by: the extracting solution, the concomitant elements in the matrix, and the pH. This process will affect the species of chromium extracted but not the amount and can generally be compensated for using stable isotope spikes. Method 6800 is beginning to receive more attention as analysts try to compensate for interconversion of the species but do not address the recovery issue of many soil matrices. We have found liquid to solid ratio makes a difference in recovery of each species from the soil. Concomitant ions and age of soil are two key factors in predicting the efficacy of the extraction efficiency. This presentation will focus on the variables associated with a good recovery of both chromium species from soil and how we use the total chromium value as a measurement of extraction efficiency.

Recovery of Chromium Species from Soils: What Factors Are Most

Important

1. Environmental and Occupational Health Sciences Institute Rutgers University bbuckley@eohsi.rutgers.edu

2. NJ Department of Environmental Protection, Division of Science, Research and Technology

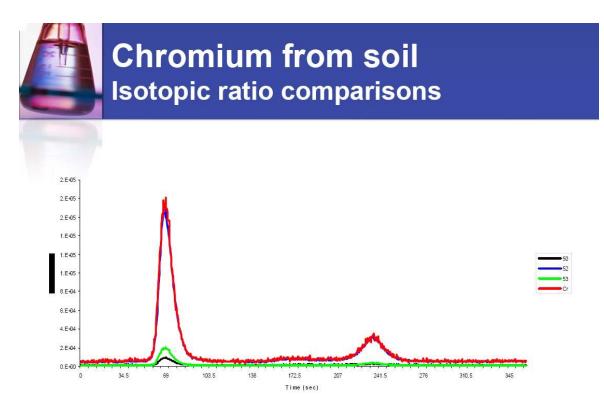

Environmental and Occupational Health Sciences Institute

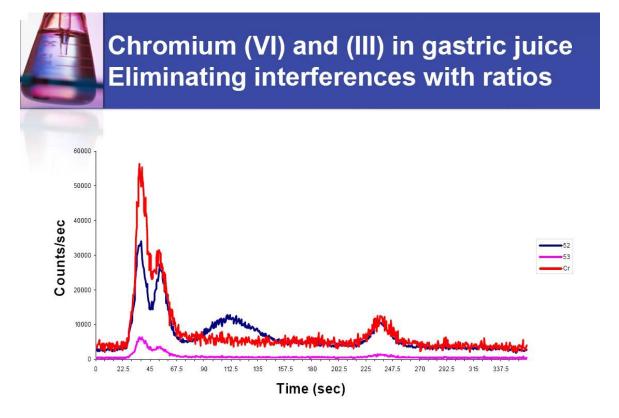

Inductively Coupled Plasma Mass Spectrometer

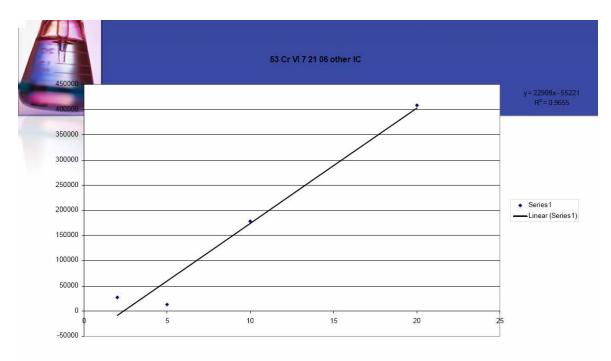

Figure 1: Four Point Calibration Curve for the Direction Injection of 53CrVI standard into IC-ICP/MS.

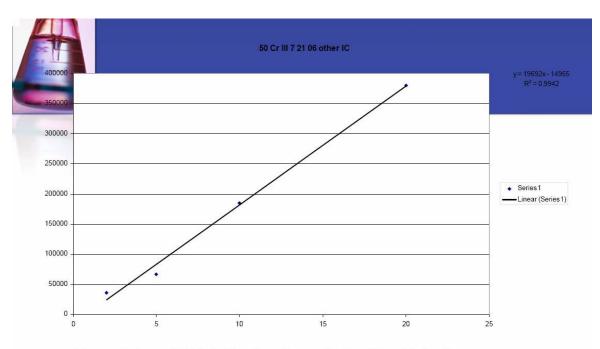

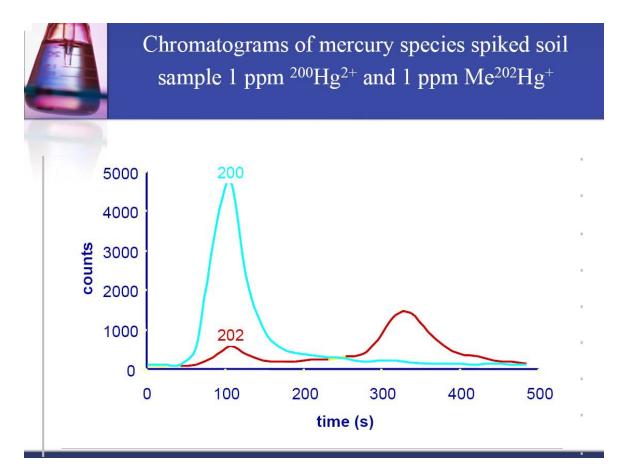

Figure 2: Four Point Calibration Curve for the Direct Injection of 50CrIII standard into IC-ICP/MS.

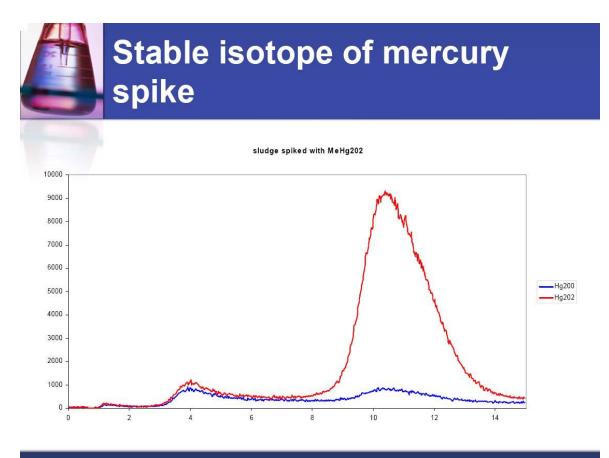

Microwave advantage

- Higher pressure and temperature
- Better infiltration of extratant into material
- "mobilization" of all material that absorb microwaves

Percent recoveries of mercury species from spiked soils

Sample	IC-ICP-MS		IC-CV-ICP-MS	
	Hg ²⁺	CH₃Hg⁺	Hg ²⁺	CH₃Hg⁺
Soil 1 (Bayonne, NJ)	94 ± 3	106 ± 5	103 ± 8	95 ± 6
Soil 2 (Aiken, SC)	107 ± 8	93 ± 6	105 ± 7	92 ± 8

Mercury recoveries from sludge spike experiment

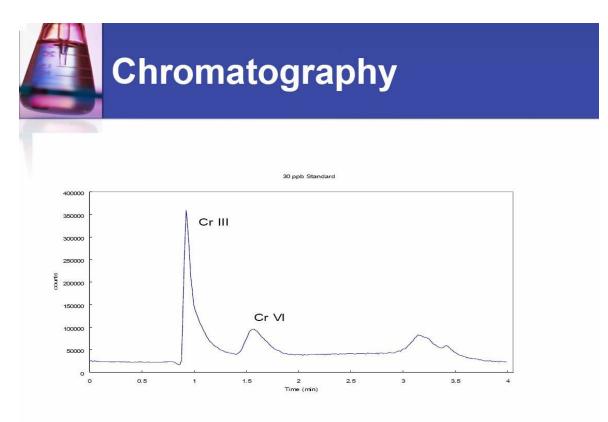

Sample	Hg2+ conc (ppb)	MeHg2+ conc (ppb)	Recovery of MeHg202
0203 ANDR	503.12	54.84	0.93
0203 CAND	N/D	26.90	1.06
0203 GRDR	106.78	155.32	0.89
0203 GRLI	N/D	48.92	0.99

- 0.08 and 0.10 g of soil
- digested with 10 mL of 100% HNO3.
- 1200 W power
- 350 psi pressure
- 180°C temperature
- 10 minute ramp time
- 15 minute hold time

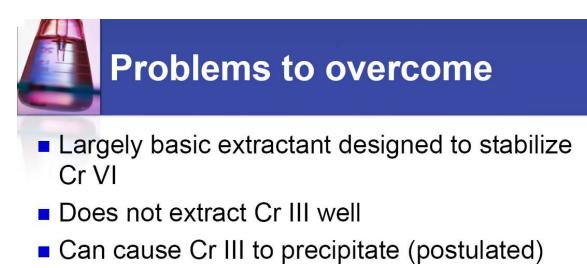

Method validation

- Need to account for both extraction loss and species changes during extraction
- Compare total chromium recovery to sum of individual species
- Look for interconversion with method 6800

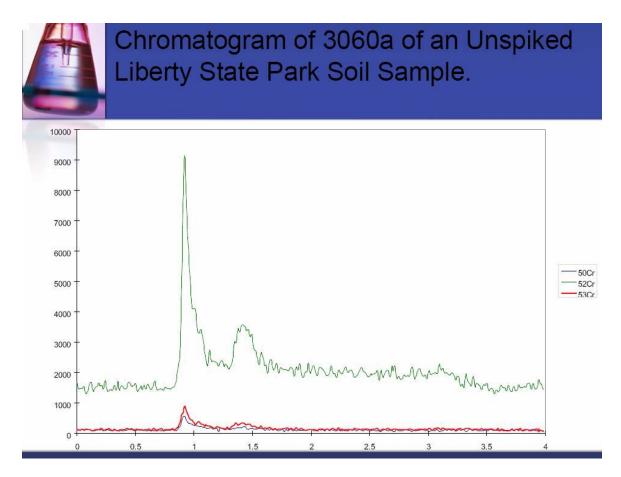

Modified 3060a Method Summary

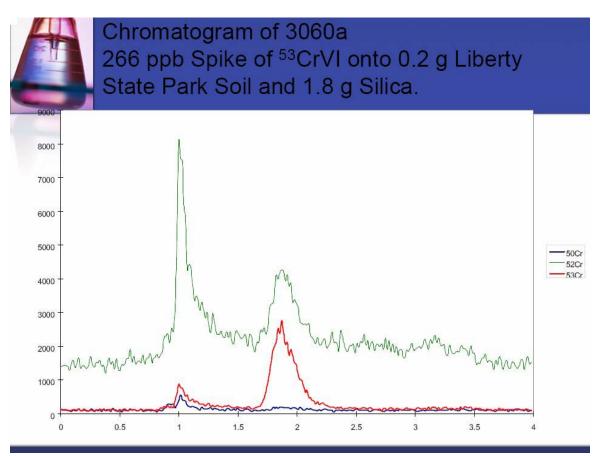

- NaOH/NaCO₃ extraction
- Extraction in microwave*
- "Soil" samples mixed with sand for dilution*
- Solution made neutral to acid**
- Extrantant solution diluted**
- Injected into IC**
- Separated on an anion exchange column**
- Redox monitored by stable isotopes
- * Modification to EPA method
- * * Our method

SPECIES ANALYSIS DURING MEASUREMENTS PROCESS

Bath, Frank; Retsch, Inc. Batzke, Matthias; Retsch, Inc. Fahrenholz, Timothy; Retsch, Inc. Kern, John; Duquesne University Kingston, K.M. 'Skip'; Duquesne University Pamuku, Matt; Retsch, Inc. Rahman, Mizanur; Duquesne University

Elemental speciation is unique in that the species of interest or the analyte being evaluated may change and become another analyte during the analysis process. This phenomenon and related parameters make species measurement one of the most challenging fields of metrology, especially when the goal is to achieve accuracy. Significant areas contributing to the lack of accuracy are the lack of certified standard materials and the lack of proven, reliable diagnostic tools. Many elemental species undergo conversion or degradation of the species of interest during measurement processes and even sometimes during sampling, storage and transport. Until recently, there have not been any effective diagnostic tool to trace the fate of species; conventional speciation methods measure the species' concentrations in the final solutions at the time of measurement but provide no information on species transformations. Knowing the transformation of the species is critical in the preparation and certification of standard reference materials and for accurate speciated measurements. Newly approved EPA RCRA Method 6800, known as Speciated Isotope Dilution Mass Spectrometry (SIDMS), facilitates to identify and enable correction for such degradations or conversions. SIDMS may also be directly applied to validate a variety of other speciated protocols to accurately measure species like methylmercury, ethylmercury and other alkylmercury species in tissues and other materials (1, 2, 7, 15). SIDMS has been demonstrated to determine the species concentrations at the time of spiking, as well as during sampling and measurement processes. The method also provides the ability to perform diagnostic analysis by isolating procedural protocol steps in specific matrices and reveal speciesshifting potential. By spiking the sample at multiple steps with enriched stable isotopes of the same species, SIDMS can identify the steps at which the species are altered (3-7).

As examples, SIDMS has been applied to monitoring the fate of methylmercury and Hg(II) and other alkylmercury species as well as Cr(III) and Cr(VI), during the sample processing and analysis steps. The results of recent studies showed that classical methods may not be able to detect alteration of the species from difficult matrix samples and sample preparation steps that cause transformation of species (3, 5, 8, 10). Recently, known pollutant-species have been found to be even more toxic, prompting lowering of the acceptable limits of these species in the workplace by OSHA.

After July 1, 2006, electronic products exported to European Union countries require that hexavalent chromium accurately measured and the allowable species limits be met before they are allowed to be sold in the EU. This new regulation is referred to as "Restriction of Hazardous Substances" or (RoHS) and is required before sales of products are allowed (14). China, Korea and many other countries have already indicated that they will impose similar species-specific limits for electronic products sold in their countries. RoHS and all other derivative regulations also require measurement of Hg, Cd and Pb. Discussion and examples of sample preparation for

these regulations will be discussed, limitation of surface techniques such as x-ray fluorescence techniques examined with respect to speciation measurement and certification.

Mercury has been demonstrated to undergo transformations between methylmercury and inorganic mercury during the measurement process (5, 8, 10). SIDMS is a method that can be generalized for most poly-isotopic species that have the potential to be transformed from species to species during the evaluation process. SIDMS has been successfully applied to measure species of poly-isotopic elements such as Cr, Hg, Se and Sn. Standards may also be produced with isotopically enriched species and used if the processes alter the species forms (9, 10).

Coal-fired power plants around the world are a dominant source of electric energy, particularly in developing nations. As much as 20% of the chromium contained in coal may be converted to Cr(VI) during power plant production of energy. Field environmental examples are presented, demonstrating the effectiveness of applying the SIDMS measurement for Cr in the coal-fired power industry (13). As a measurement and diagnostic tool, SIDMS has been standardized and approved as EPA method 6800, and as part of the new Method 3200 (10, 11, 15).

These new EPA stable isotopically-based methods provide new tools and assist with some of the uncertainty in speciated environmental measurements. The general method is described and applications to both Cr species and Hg species are demonstrated in the latest draft of the method. In applying Method 6800, commercially available species-specific reagent and standard kits simplifies the entire SIDMS protocol and make it possible to implement Method 6800 in a routine fashion. Software in these kits, with equations keyed to enriched stable isotopes of each kit improve, simplify and accelerate quality assurance, data acquisition and final calculation steps. A tutorial SIDMS-software is now available from the EPA and Duquesne University to assist in understanding the equations associated with Method 6800. This past year analyst proficiency testing was made available to commercial analytical laboratories in order to enable high volume speciation analyses in a routine and automated fashion. The efforts of proficiency-certified laboratories described and some of the data of their speciation analysis work are presented.

Some COPR or chromium ore processing residue wastes that are concentrated or that have been mixed with other soils are unstable even after treatment. Recent unpublished work by Kingston, co-workers and collaborators, demonstrated that some well-known treatment process do not keep Cr species stable and transformations from Cr(III) to Cr(VI) occur in time frames from several years to several weeks time.

New Jersey is in the midst of many large remediation projects that involve several competing technologies that attempt to contain the Cr(VI) in various inert forms. EPA Method 6800 is being used to analyze these samples and forms. New Cr(VI) contaminants in major western states are emerging in roads that are paved with Cr(VI) leaching materials which contaminate soil in the surrounding communities serviced by these roads (13). Interferences and contributions from the soil chemistry in samples frequently skew the result of several analytical methods, making decisions difficult. Advanced species measurement methods will be demonstrated and application to critical environmental measurement needs will be described.

USING METHOD 6800 FOR CHROMIUM (VI) ANALYSIS

Bruce Ph.D., Mark; Severn Trent Laboratories Reinheimer, Bill; Severn Trent Laboratories Vicini, Rusty; Severn Trent Laboratories

The Kingston research group at Duquesne University developed Method 6800 several years ago. Several research laboratories have used this speciated isotope dilution mass spec method to determine chromium (VI) in soil and water samples. Application by commercial environmental laboratories has been very limited. Complete commercial implementation includes the following areas: acquisition of ion chromatograph and ICP/MS, hardware and software interface of instrumentation and data systems from different instrument providers, acquisition of isotopically label standards, sample preparation, instrumental analysis, raw data collection, quantitative isotope ratio calculations and final data reporting.

This paper will describe STL's experience of bringing what appears to be complex methodology and instrumentation into a production laboratory setting where accuracy, sensitivity and productivity goals must be met.

The Commercialization of Method 6800- Speciated Isotope Dilution Mass Spectrometry for the Determination of Hexavalent Chromium

Albert F. Vicinie III,* Mark Bruce, PhD. ** William Reinheimer* *Severn Trent Laboratories, Inc., Pittsburgh, PA; **Severn Trent Laboratories, Inc., North Canton, OH

ABSTRACT

Method 6800 has recently been approved for the determination of the various species of metals such as Chromium III and Chromium VI. It is a hyphenated technique that couples ion chromatography (IC) with Inductively Coupled Plasma/Mass Spectrometry (ICP/MS). To date use of this method has been primarily in academia and limited project support. The method offers two primary challenges. It utilizes a mathematical approach to deconvolute the species that is unique to other traditional methods utilized in commercial environmental methods. Also the method does not specify in detail quality control practices and deliverables to be performed and provided to allow the data user to effectively evaluate the data set. This paper identifies the primary differences in this method from traditional as well as proposed QA/QC practices along with a deliverable to allow effective data validation and assessment.

INTRODUCTION

Method 6800 may be utilized to determine the total metal content for various elements using isotope dilution mass spectrometry (IDMS) and determining the elemental species for numerous metals using speciated isotope dilution mass spectrometry (SIDMS). We are focusing our discussions on the analysis of soils, leachates and waters for hexavalent chromium (Cr VI) using the SIDMS approach of 6800.

This method is providing investigators much new and valuable additional information to allow the assessment of hexavalent chromium in soil matrices that are not suitable to provide data of known and acceptable quality with other analysis methods in order to support environmental decisions. Method 6800 provides solutions to the analytical challenges and refers to the base technology methods and Chapters One and Two of SW-846 as well as individual project plans for the development and incorporation of appropriate quality control procedures. We discuss in the following paragraphs suggested practices and procedures that will provide additional information to the investigators and regulating community to assist in assessing the data generated by this method.

Specified Quality Control Measures

Method 6800 SIDMS specifies the following quality control measures explicitly.

Dead Time Determination- This determines the interval during which the detector and its associated counting electronics are unable to resolve successive pulses. The measured counts are lower than the true counts if no correction occurs. Current instrument operating software allows this to be set and controlled for each instrument. Alternatively method 6800 provides guidance on determining the dead time. This should be performed/evaluated daily.

Mass Bias- This is the deviation of the measured isotope ratio from the true value caused by the differential sensitivity of the instrument to mass. This effect may occur in the ionization process or from differential transition/detection by the mass spectrometer. The resultant mass bias factor is the number used to correct for the mass bias of the measured isotope ratios and is determined by performing 4 replicate measurements of an isotopically certified standard. We are proposing that this be performed at the beginning of each analytical sequence and at the end of each analytical sequence or every 4 hours whichever is more frequent.

Background Blank- This is the background associated the solutions used for sample dilution (eluent) and with the chromatographic baseline.

Preparation (Reagent) Blank- This is blank laboratory grade water that is carried through the complete preparation procedure and contains the same volumes of reagents as the sample solutions. We propose that this be performed at a minimum of 1 per sample batch with batch size not to exceed 20 samples that is consistent with normal quality control practices.

These are QC measures that are not routinely included in the base ICP/MS methods such as SW-846 6020 but are inherent to the performance of this method. There are no existing criteria to assess their performance, nor any precedent in presenting them as part of a deliverable. The dead time determination ensures that the measurements are made within the appropriate range and the mass bias factor becomes part of the solution to solving the equation to determine the actual isotope ratios used for the calculation.

Non-Specified Quality Control Measures

These measures are not directly specified as part of method 6800 for Cr VI or other elements. We are proposing the following measures that are either normally included in laboratory/project quality plans, part of the base methods such as method 6020 for the use of ICP/MS in the determination of metals in waters and soils or other related hexavalent chromium methods.

1. Holding Times

- a. For soils we default to existing published guidance in method 3060A of 30 days for soils stored cool at 4 deg C. Once extracted the alkaline digestion has been demonstrated to be stable for 7 days by this same method. Method 3060A is the alkaline digestion sample preparation method used to prepare soil/sediment samples for analysis using method 6800 for Cr VI.
- b. For waters being analyzed by the routine method of 7196A these are typically collected unpreserved and submitted for analysis within a 24 hour holding time. Due to the more complex nature of method 6800 this may be impractical in routine use. USEPA method 1636 provides that aqueous samples preserved by pH adjustment to > 9 may be stored for up to 30 days at 4 deg. C. We recommend this preservation technique for any project associated field QC samples such as equipment blanks to be analyzed by method 6800 for Cr VI.

2. Instrument Performance

- a. Cross Calibration of Mass Spectrometer Detector- this determines levels at which the detector switches from pulse to analog measurements and is related to the dead time of the instrument. We are proposing that this be performed each day of instrument operation for this method. There are no performance limits associated with this action.
- b. Tune Check- (Performance Report) this tunes the mass spectrometer to a known material. We are proposing that the tuning criteria for the mass spectrometer be the same as that published in USEPA method 6020.
- c. Dynamic Range Determination- for screening samples using the Time Resolved Analysis (TRA) mode we propose analyzing 4 aqueous standards of Cr VI at concentration of 10, 50, 100 and 200 ug/L to provide quantitation of the screened samples that have not been spiked with the enriched isotopes. Data will be acquired using the 50, 52 and 53 amu masses with quantitative analysis performed using the 52 amu mass. There are no criteria set to evaluate this calibration and as it is only used to provide screening level data to allow appropriate spiking of enriched isotopes no criteria is proposed. We are however proposing to bracket the analytical sequence with a 50 ug/L solution that will be analyzed and quantitated against the instrument calibration and evaluated using method 6020 criteria. Samples should be diluted if necessary and analyzed within the range identified.
- d. Instrument Sensitivity- While not specified we recommend that instrument sensitivity be evaluated using aqueous standards of either Cr III or Cr VI by performing 7 replicate analyses and evaluating the data for the mean and standard deviation. No criteria is provided but we recommend utilizing the same criteria as provided for evaluating MDL studies in 40 CFR 136 to ensure the analysis is able to reliably be differentiated versus a blank. We recommend this be performed on a quarterly basis. Example data is provided in Table 1.

3. Method Performance

- a. Accuracy- We are proposing the analysis of a soil sample of known concentration such as an NIST SRM or a material provided by a NELAC approved PE vendor such as ERA or equivalent. These samples should be analyzed at a minimum of 1 for every batch of samples prepared through the alkaline digestion with batch size not to exceed 20 samples. Manufacturer provided criteria should be used to evaluate performance.
- b. Detection Limits- Due to the unique nature of this method as it applies mathematics to the direct measurement of the isotopic ratios which are spiked into each sample at known quantity the traditional method detection study as described in 40 CFR 136 does not directly apply to this method as there will by the nature of the method always be detectable levels of isotope. However we conducted and are proposing that a traditional MDL study be conducted through the alkaline digestion of a Cr VI spiked sample that is not spiked with the enriched isotope to provide an idea of the level at which the naturally occurring chromium isotopic abundance can be expected to be detected. We have provided an example of this data in Table 2.

- c. Matrix Effect- As each sample is spiked with both a Cr III and Cr VI species the matrix of each sample is able to be evaluated and addressed by the method. As such there is no reason to include additional MS/MSD samples that are typically included in analytical batches.
- d. Interference Checks- ICSA/ ICSB interference checks that are commonly included in the ICP-AES and ICP/MS are not included in this method and not required as there is chromatographic separation, confirmation of retention time and mass spectral evaluation of isotope ratios at 50, 52 and 53.

CONCLUSIONS

Method 6800 is a much needed and useful tool in providing a more definitive evaluation of hexavalent chromium in soil samples that due to their matrix may not be able to be accurately characterized by other traditional methods. As this method provides a novel solution to these challenges it also presents challenges to the analytical community as well. These challenges are primarily involve the training and understanding of the analysts and data users to ensure the highest quality of data is generated and that the data can be assessed appropriately. We have proposed appropriate measures to allow for the evaluation of data using this method and that will allow it to be reproduced and evaluated.

ACKNOWLEGEMENTS

The authors would like to acknowledge Dr. H.M. "Skip" Kingston and Dr. G. M. Mizanur Rahman of Duquesne University, Department of Chemistry and Biochemistry, Pittsburgh, PA 15282 for all of their training and assistance in transitioning this analytical method into a commercial environmental laboratory.

Leaders in Environmental Testing

The Commercialization Of Hexavalent Chromium Determination Using Method 6800 With Speciated Isotope Dilution Mass Spectrometry (SIDMS)

NEMC- August 2006

Albert "Rusty" Vicinie William Reinheimer Mark Bruce Ph.D. Nasreen DeRubeis

Common Commercial Hexavalent Chromium Methods

Water

Colorimetric

– SW 846-7196A

– SM 3500 B

Ion Chromatographic

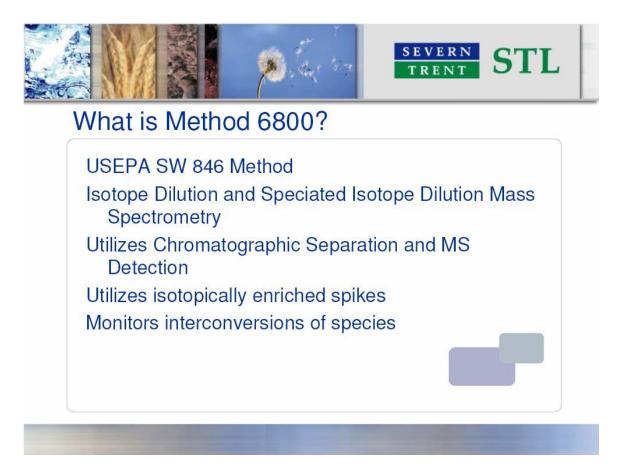

- SW 846-7199
- SM 3500 C
- EPA (OW) 1636

Colorimetric

Soil

- SW 846-3060A/7196A

Ion Chromatographic - SW 846-3060A/7199

Why Method 6800?

Addresses matrix related effects
Corrects for interconversion of species during sample preparation and analysis
Diagnostic tool for the evaluation of species altering procedures
Permits evaluation and validation of traditional speciation data

Aspects of Method Implementation

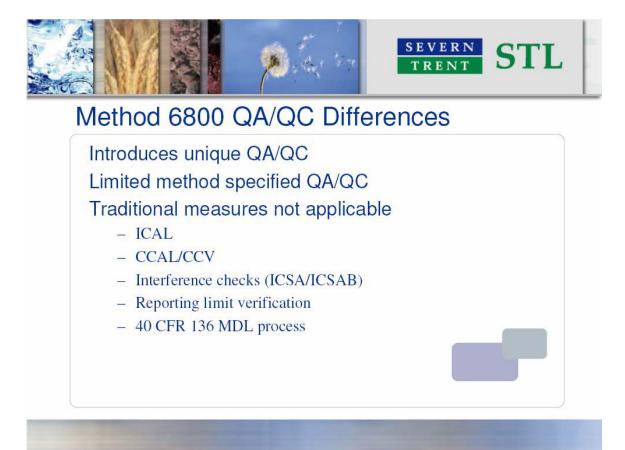

Sample preparation technique

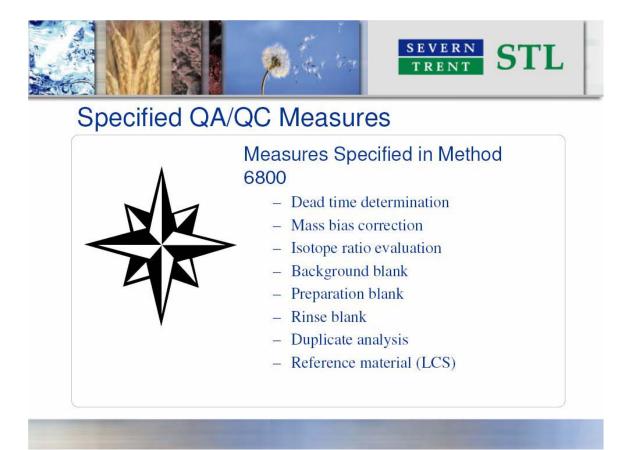

- Extraction efficiency/stability

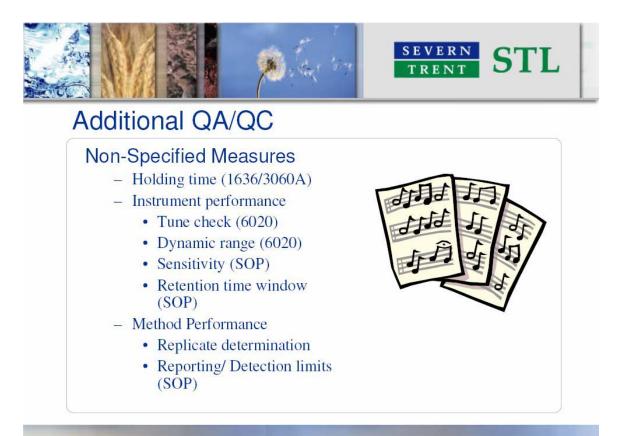

Instrumental analysis

- Interferences
- Sensitivity
- Linearity
- Dynamic range
- Carryover/contamination
- Stability/drift
- Reproducibility

Data reduction and evaluation

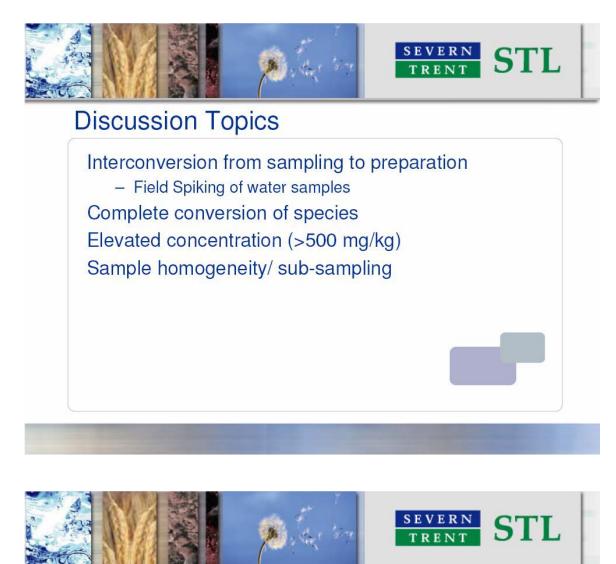

Method 6800 Deliverables

- Cross Calibration Report (Dead Time Verification)
- Mass Calibration Verification
- Isotope Certificate
- Reference Material Certificate

- Sample Data
- Digestion Log
- Chromatograms
- Calculation
 Worksheets
- EDD results only

Challenges

✓Instrumentation

- Ion chromatograph
- ICP/MS

✓Training

- Novel method principles

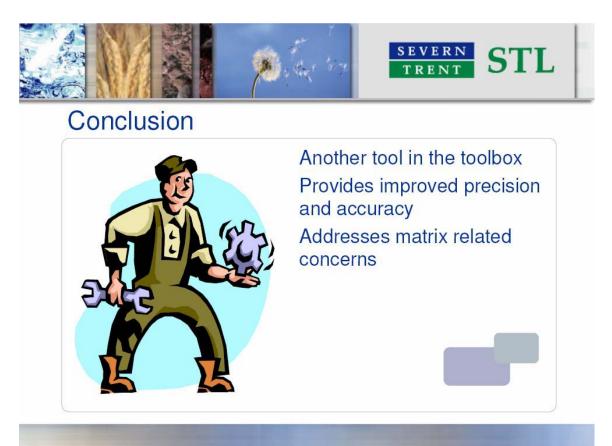

✓Data Reduction

 Complex mathematical deconvolution

✓ Certification

Market Acceptance

THE HISTORY OF NELAC

Lara P. Autry US EPA August 30, 2006

OVERVIEW

- Background/History
- Structure
- Program Goals
 - Self-Sufficiency
 - Performance Approach
 - Growth/Outreach
- Contact information

BACKGOUND/HISTORY

- Why was NELAC/NELAP created?
 - Inconsistent/nonexistent inspections;
 - No reciprocity among states;
 - Loss of accreditation in one state does not affect status in another;
 - Accreditation in all areas is not available;
 - Customers have no access to information;
 - Accreditation not recognized in foreign markets; and
 - Programs generally viewed as inadequate.

NATIONAL ACCREDITATION TIMELINE

- Report to Congress 1986
- Committee on National Accreditation of Environmental Laboratories (CNAEL)
 July 1991 – July 1992
- State EPA Focus Group
 January 1993 September 1994
- NELAC/NELAP February 1994 present
 - 1994 1997 Development Only
 - 1997 June 5, 2003 Standard Development/Adoption
 - June 6, 2003 present Adoption Only
- Environmental Laboratory Advisory Board (ELAB)
 - 1995 present

PROGRAM COMPONENTS

- Standards Adoption (NELAC)
 - Proficiency Testing Board
 - Standards Review Committee
 - Membership & Outreach Committee
 - Nominating Committee
 - Special Task Groups or Committees (Varies)
- Standard Development Organizations
- Program Oversight (NELAP)
 - Accrediting Authority Committee
 - Accrediting Authority Review Board
 - Regional Assessors
- Advisory Group (ELAB)
 - Environmental Laboratory Advisory Board

STABILITY FOR NELAC STANDARD

- July 1, 2005 June 30, 2009
 - August 2004 Version
 - C&B
 - 2003 Version
 - Chapter 1
 - Chapter 2
 - Chapter 3
 - Chapter 4
 - Chapter 5
 - Chapter 6
 - 2002 Version
 - Chapter 7 (only version)

PROGRAM GOALS

- Self-sufficiency of the program.
- Performance approach (i.e., method flexibility) to assure that standards foster the production of data of known and documented quality.
- Growth to provide consistency.

SELF-SUFFICIENCY

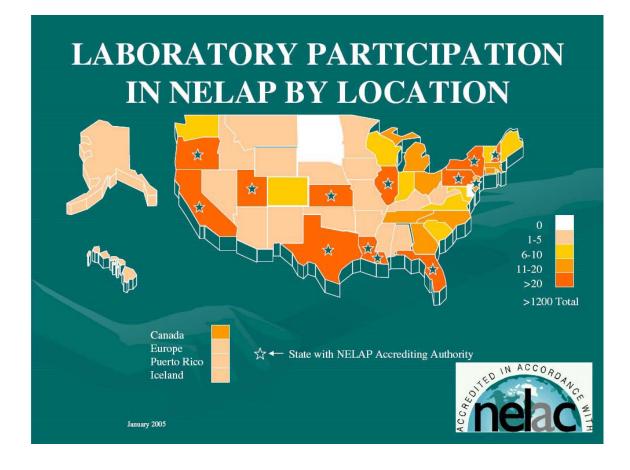

- Separation of Administrative Functions
- Cooperative Agreements
 - Standards Development and Technical Support Agreements
 - NSF International
 - Institute for National Environmental Laboratory Accreditation (INELA)
 - Program Administrator
 - National Forensic Science and Technology Center (NFSTC)

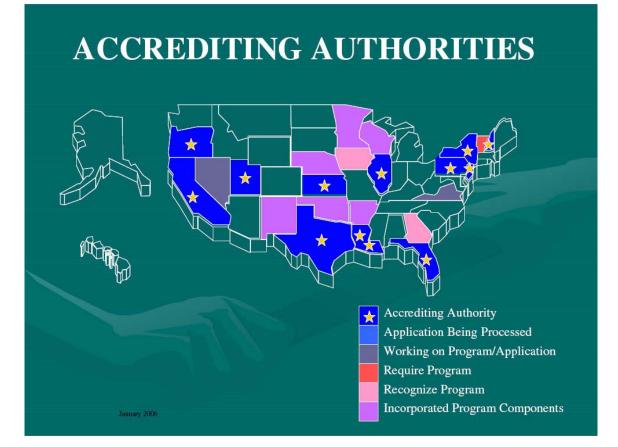

PERFORMANCE APPROACH

- Assures the Production of Data of Known and Documented Quality
- Agency Moving Forward Again
- Pilot Programs Being Established
- Incorporated into NELAC Standard
- Training is Available

TRAINING COOPERATIVE AGREEMENT

- Awarded to Independent Laboratories Institute (ILI)
- Focus is on Special and Practical Knowledge for Laboratory Accreditation
- Teaching Methods:
 - Classroom Style Training
 - Workshops/Conferences/Roundtables
 - Computer-Based Training

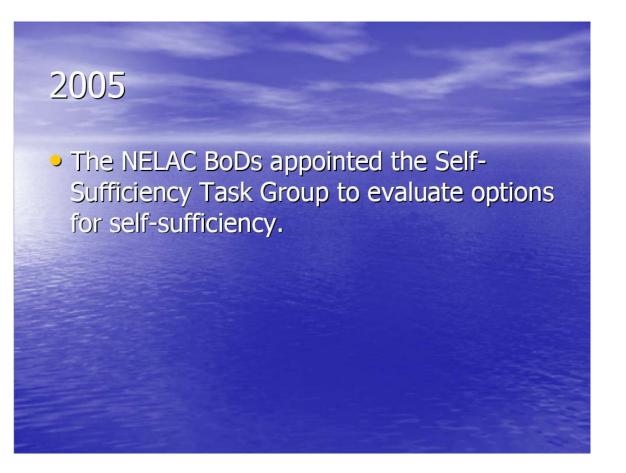

AGENCY RECOGNITION OF NELAC PROGRAM

- Regional laboratories being accredited.
- Program Office laboratories responding to laboratory competency requirements.
- Working on mechanisms to recognize and reward those with accreditation, certification, and/or quality programs.
- Working with all Program Offices to integrate individual programs into one National network.

THE FUTURE OF NELAC PROGRESS UPDATE

NEMC Arlington, VA August 2006 Aurora Shields

2006

 The NELAC BoDs appointed the special committee on National Accreditation to evaluate why the goal for National Accreditation had not been accomplished and outline strategy to succeed

UPDATES

Special Committee on National Accreditation
Self-Sufficiency Task Group (SSTG)

NELAC Board Special Committee on National Accreditation

Committee Members and Representation

- Gary Ward commercial laboratory community (ACIL)
- Kenneth Jackson NELAP State
- Marlene Moore third party assessor/contractor
- Paul Kimsey state primary laboratories (APHL)
- Susan Wyatt non-NELAP State
- James Jordan ELAB
- Kevin Coats DOD
- Mark Carter PT Vendor
- Lara Autry EPA

Special Committee Task

- Evaluate the Committee for National Accreditation of Environmental Laboratories (CNAEL) recommendations; and
- Determine why the goal for National Accreditation had not been accomplished and outline strategy to succeed

Has NELAC achieved CNAEL goal as a national accreditation program ?

 CNAEL Recommends – establish program that has federal oversight and is implemented by states and/or third parties
 Key elements evaluated – CNAEL Report conclusions summary (next slide)

CNAEL Report Elements Evaluated

- Reciprocity and leveling of differences between the various state programs
- Uniform standard for all aspects of laboratory performance
- Consistent laboratory audits
- Uniform national PT program
- Minimize negative effects on the operation of existing state lab accreditation programs
- Minimize outlay of federal/state funds and operation through self-supporting mechanism

Position Paper Conclusion/ Action Item

- Key Conclusion need buy-in by EPA Program Offices
- Action Item Report (Committee) and letter to EPA Program Offices (Board)
- Report "A Proposed Partnership to Achieve Data Quality Assurance through a National Laboratory Accreditation Program" (May 25 2006)

Report Key Elements

- Purpose
- History
- NELAC/NELAP Accomplishments
- Areas for Improvement
- Common Goals
- "A Place to Start"
- Benefits to EPA Program Offices
- Conclusion

Special Committee Report

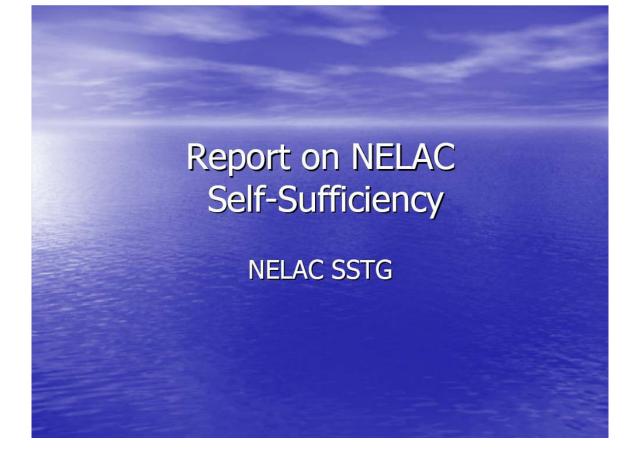

- Purpose "We suggest that EPA and the states can most effectively and efficiently meet their data quality assurance mandates through the existence of a national laboratory accreditation program and requiring that all environmental compliance monitoring data be generated by laboratories accredited by this program."
- Common Goals "To be successful, NELAC needs EPA program offices to participate as truly engaged partners with a commitment to harmonize all Agency and NELAC requirements and programs designed to ensure the quality of all compliance data submitted to and used by EPA."

Special Committee Report Benefits to EPA Program Offices

- Harmonization all current EPA and State accreditation programs
- Recognition and coordination of state and federal accreditation programs
- Management all aspects PT programs
- Training lab assessors, management and technical personnel
- Mentoring state and federal accreditation programs
- Mentoring commercial, industrial, municipal, state and EPA laboratories
- Forum to promote nationally consistent lab evaluations
- National database of accredited labs and PT information

Special Committee Report Conclusion

- "As EPA and the states are mandated to ensure the quality of data that are used to assess and ensure regulatory compliance, it is essential that the national laboratory accreditation program be directed solely by state and federal personnel in an open process with appropriate consultation and input from all affected stakeholders."
- "The NELAC Board wishes to explore with EPA its vision as to how the EPA can best participate to help ensure the success of the national environmental laboratory accreditation effort."

- Aurora Shields
- Judy Duncan
- Alfredo Sotomayor
- Ann Marie Allen
- Silky Labie

- Art Clark
- Barbara Finazzo
- Marcia Davies
- Patricia Hurr
 - Lara Autry

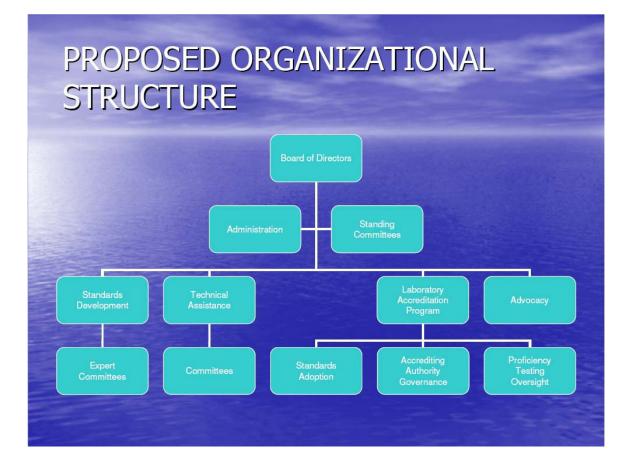

Advise the NELAC Board of Directors regarding the development of a plan for NELAC/NELAP self-sufficiency.

Draft Vision, Mission, and Purpose

- Provide a true national accreditation system.
- Foster the generation of environmental data of known and documented quality to assist efforts towards protecting and improving human health and the environment.
- Promote professionalism in the field of environmental analysis through quality, leadership, and training.

CHARACTERISTICS

- Incorporated, Not-for-Profit
- Contains Consensus Based International Standards
- Promotion of Professionalism
 - Quality
 - Leadership
 - Training and Education
- Products
- Services

Interim Timeline Transition

Proposal for NELAP Director:

- AARB to assume the programmatic duties.
- NELAC Board assume oversight.
- Administrative assistance provided by NFSTC.

Proposal for NELAC Director:

- PT Board oversees PTOB/PTPA.
- NELAC Board continues oversight.
- Administrative assistance provided by NFSTC.

Solicit Stakeholders

 NFSTC solicited interest from organizations.

 Informed community the SSTG was open to offers of assistance.

INELA

Similar/Compatible:

- Purpose/Mission/Vision,
- Characteristics,
- Products, services, activities,
- Infrastructure, and
- Constituency.

Recommendations

NELAC and INELA approved MOU.

- Non-binding agreement to explore a partnership between NELAC and INELA.
 Duration 6 months.
- Appoint a Partnership Planning Team
 - Team will submit a report and recommendations

National Accreditation for Environmental Testing

The Changing Role of INELA in Standards Development

Agenda

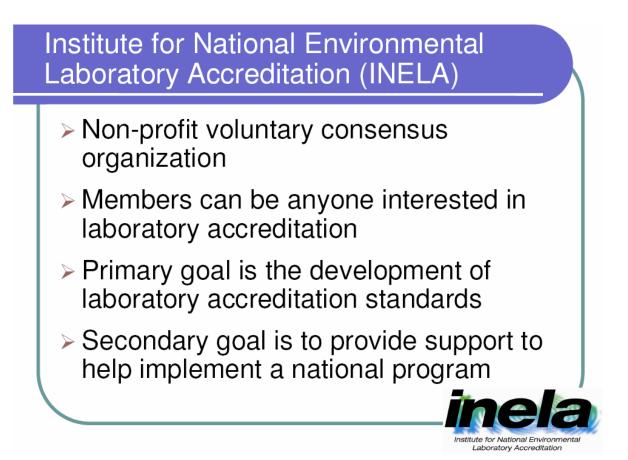

- About INELA
- The INELA Process for Standards Development
- INELA's other activities
- How things will change

INELA History

- Need for a non-profit identified in June 2000
- identified No organization came forward
- Small group saw the need and decided to form a non-profit
- INELA formed in May 2001

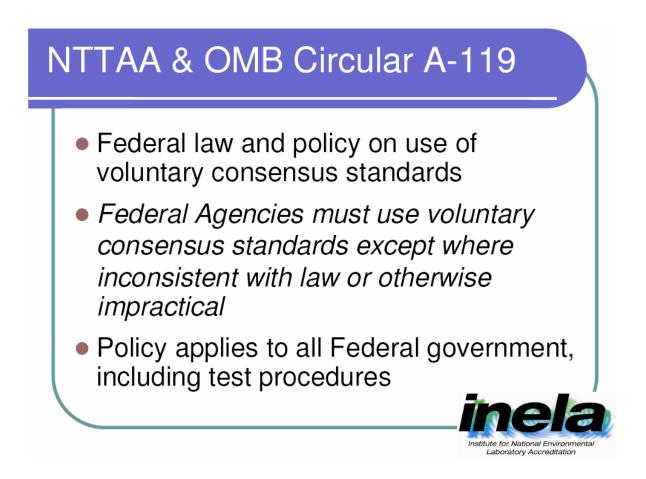

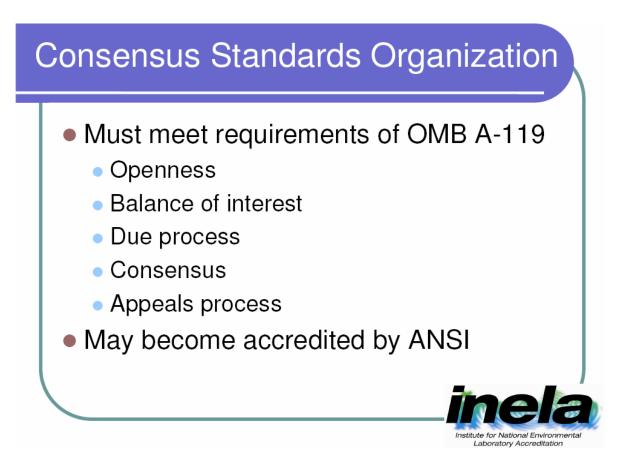

The Role of Consensus Standards

National Technology Transfer & Advancement Act OMB Circular A-119 Consensus Standards Organizations American National Standards Institute

Basis of INELA Policy

- ANSI requirements for accreditation of voluntary consensus standards organizations
- Policies of ASTM
- Policies of the National Fire Protection Association, an organization comparable to INELA

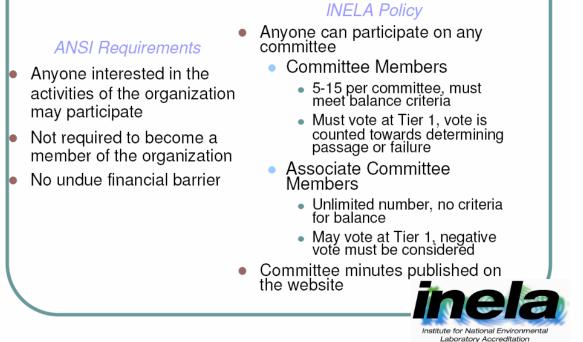

General Principles

- INELA expert committees write the standard, based on input from multiple sources
- Six Expert Committees
- Two-tier voting process
 - Expert Committee
 - General membership

Openness

Balance of Interest

ANSI Requirements

- Participants from diverse interest categories
 - No single interest category constitutes a majority of the membership of the consensus body

Standards development process shall not be dominated by any single interest category, individual or organization

INELA Policy

- Committee Members selected to provide balance
 - Serve on only one committee
 - Represent stakeholder group
 - State accrediting authorities/regulators
 - Federal accrediting authorities/regulators
 - Laboratories
 - Other interests
 - No stakeholder group can be a majority

Due Process & Appeals

Requirements

INELA Policy

- Anyone can appeal any action of INELA
- Appeal process uses ANSI guidance
- All comments and their disposition are public information
- Any person with a direct and material interest has a right to participate by:
 - Expressing a position and its basis
 - Having that position considered
 - Having the right to appeal
- Identifiable, realistic, and readily available appeals mechanism for the impartial handling of procedural complaints regarding any action or inaction

Consensus

Requirement

•General agreement, but not necessarily unanimity.

• Process for attempting to resolve objections by interested parties

•Fair consideration of all comments/objections

•Disposition & reasons provided to commenter

•Consensus body members are given an opportunity to change their votes after reviewing comments.

INELA Policy

- All negative comments must be addressed at Tier 1
 - Can be ruled persuasive, nonpersuasive, or hold for next revision cycle
- Any member can appeal
- Majority vote of all INELA members required for approval of Standard

Approach for Standards Development

- Flexible format simplifies use, modification & new sector addition
- Sufficient time for development, review and adoption
- Full stakeholder involvement at every step

ISO Standards 17011 and 17025 are the foundation

Cycle for Standard Development

- Committee develops draft language
- Language provided to membership for review and comment (Working Draft Standard)
- Committee redrafts Standard, and publishes Draft Interim Standard
- Membership vote
- Consideration of comments
- Membership votes on Interim Standard
- Appeals considered
- Standard approved

Institute for National Environme Laboratory Accreditation

The 2006 INELA Draft Interim Standards

- Environmental Sector
 - Volume 1: Laboratory Requirements
 - Volume 2: Accreditation Body
 - Volume 3: Proficiency Testing
 - Volume 4: Proficiency Testing Oversight
- Field Sampling and Measurement Sector
 - Volume 1: Requirements for FSMO
 - Volume 2: Accreditation of FSMO

Modules in Volume 1

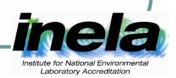

- Accreditation Process
- Proficiency Testing
- On-site Assessment
- Quality System: General Requirements

- Asbestos Testing
- Chemical Testing
- Microbiological
- Radiochemical
- Toxicology

Where are we in this process?

- Draft Interim Standard published in July
- >130 votes and >1000 comments received
- Comments discussed in INELA meeting in Kansas on August 17 and 18

Nature of Comments

- Editorial
- Specific technical comments
- Fundamental issues to be resolved
 - Use of ISO language
 - Generic vs "NELAC" standard
 - Improvement over 2003 NELAC

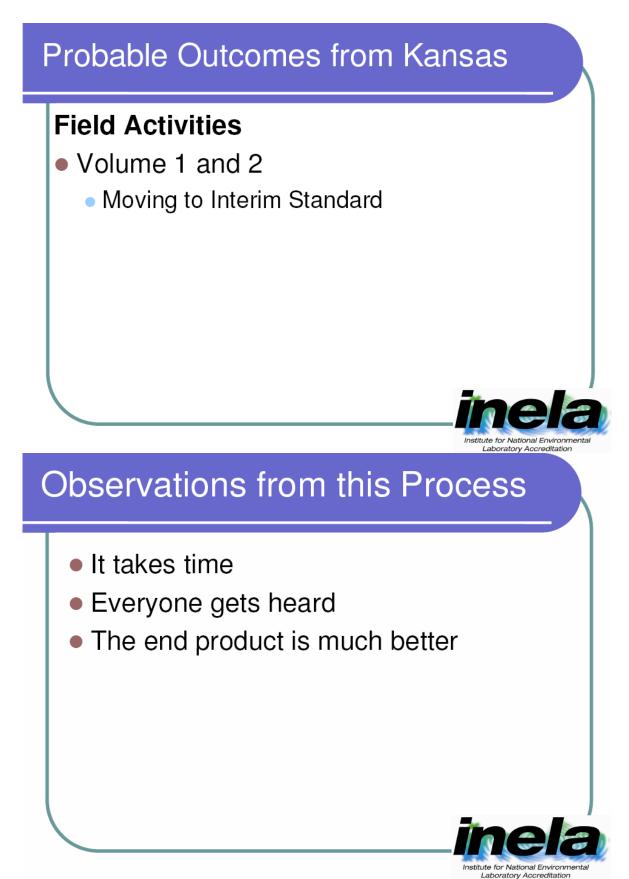

Probable Outcomes from Kansas

Environmental

- Volume 1 (Lab)
 - Modules 1 and 2 will become guidance
 - Modules 3 through 9 back to Draft Interim Standard
- Volume 2 (Accreditation Body)
 - Moving to Interim Standard
- Volume 3 (PT)
 - Back to Draft Interim Standard
- Volume 4 (PT Oversight)
 - Become guidance

1119

Next Steps for the INELA Standards

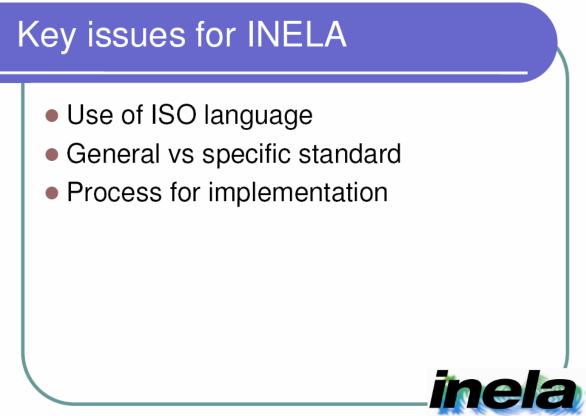

- New Ballot on December 4
- Comments considered in meeting in Denver on February 1 and 2
- Final standard approved in 2007

Impact of NELAC Effort on INELA

- Standards development may become part of a much larger effort
- One primary internal customer
- Minimal changes to policy and committee structure
- May speed up implementation
- Bring consensus process into NELAC

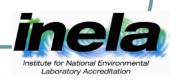

Institute for National Environmental Laboratory Accreditation

Ways to Participate

- Send a comment to the committee chair
- Come to a meeting and actively participate
- Join a committee and actively participate
- Vote negative with comment
- Vote positive with comment

INELA's Other Activities

To support the implementation of a national accreditation program

Implementation Support

- More Than a CSDO: INELA's Involvement Does Not End with Standards Passage
 - ► Training
 - Seminars
 - Small Organization Assistance
 - National Database
 - Mentor Program
 - >Website

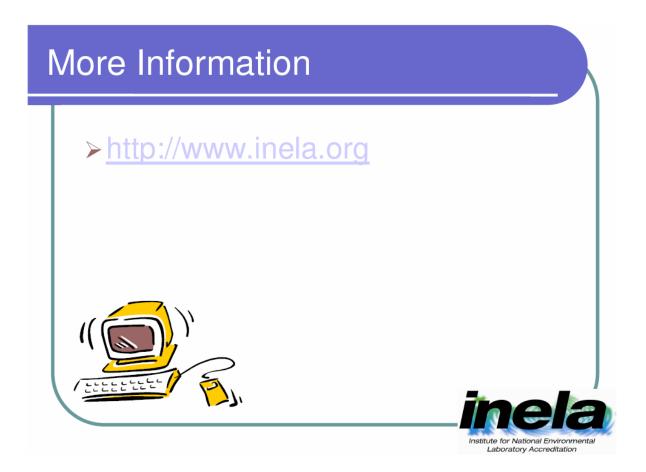

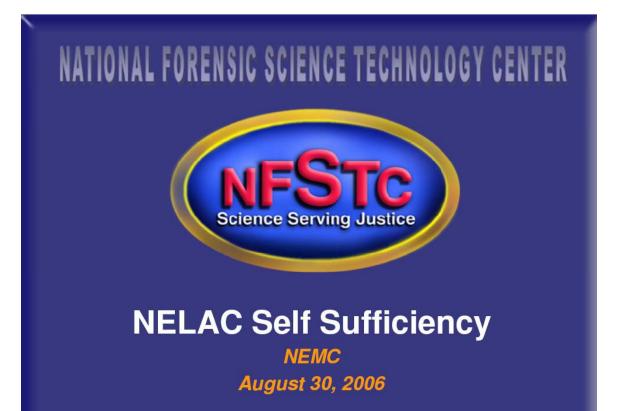

Impact of NELAC Effort

- Reorganization of INELA committee structure for technical assistance
- Migration/reorganization of website
- Increased focus on advocacy
- More assistance for small labs and states

Better communication and operation

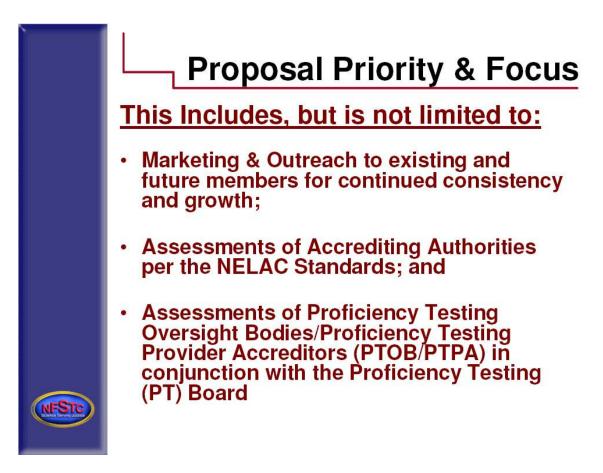

Proposal Priority & Focus

Solicitation No. EPA-ORD 25357:

"Development and implementation of a strategy and implementation plan for the long-term operation and sustainability of the NELAC National Environmental Laboratory Accreditation System"

CFDA No. 66.510

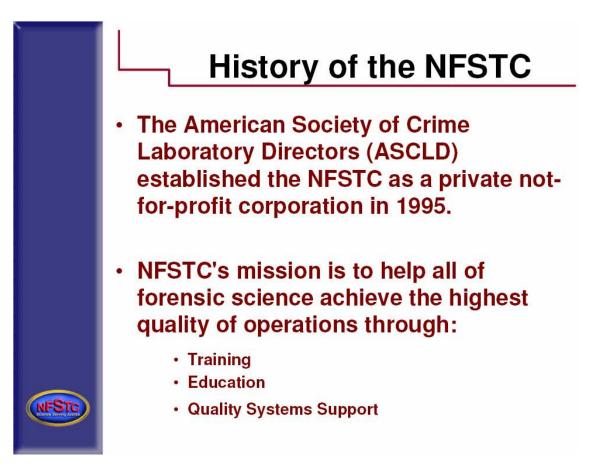

Proposal Priority & Focus

"Data management to assure the production of data that is of known and documented quality"

 Includes Quality Assurance Project Plan (QAPP) that outlines the steps that will be taken to adequately address data management issues within the program.

Corporation Members

- American Society of Crime Laboratory Directors
- American Society of Crime Laboratory Directors/ Laboratory Accreditation Board
- Bureau of Alcohol Tobacco and Firearms
- Drug Enforcement Administration
- International Association for Identification
- American Academy of Forensic Sciences
- American Board of Criminalistics
- University of South Florida
- University of Central Florida
- Saint Petersburg College
- Florida International University/International Forensic Research Institute

NFSTC

- Established by ASCLD in October 1995
- Purpose defined in Articles of Incorporation is:

In furtherance of the aforementioned purposes, the Corporation's purposes shall include the training, education and certification of persons engaged in providing forensic analysis in support of law enforcement and the accreditation of governmental and private laboratories.

- Separate accounts for Federal and cost-recovery services
- Board decided in 2003 that organizational separation was needed to
 - Relieve cost recovery side of the overhead imposition
 - Clarify the separation of activities to the outside world
- Forensic Quality Services incorporated as non-profit in 2003

NFSTC and Accreditation

- In keeping with defined purpose, NFSTC offered from the outset:
 - Support to public crime labs seeking ASCDL/LAB accreditation, including over \$250,000 from the NIJ Cooperative Agreement
 - Support to DNA sections and private labs that did not meet the ASCLD/LAB requirements in 1996
 - Sections of lab
 - Private
 - Support was in form of Certificate of Compliance with DNA Advisory Board standards

 Florida Racing Laboratory followed a year later

NFSTC and ISO

- Chose to respond to these requests by offering ISO accreditation supported by ILAC Guide 7 (Racing lab) and ILAC Guide 19 (NEIC)
- Private laboratories then came on board, mostly DNA testing
- NFSTC was offering complementary service to ASCLD/LAB's non-ISO service to public crime laboratories

- Next development came through request from GBI
 - ISO 9001 certified
 - Introduction of ISO/IEC 17025 as replacement for Guide 25 meant that they could dispense with ISO 9001 certification and deal with the quality system management aspects through NFSTC ISO accreditation

NFSTC, FQS and FQS-I

- NFSTC separated its cost recovery services by creating a class in its accounts titled "FQS" (Forensic Quality Services)
- FQS operated the accreditations for NFSTC from 2001
- FQS applied for recognition by NACLA in 2002, granted in 2004
- Condition of NACLA recognition was separation of FQS consultancies and ISO accreditations

 When FQS was established as separate company it preserved the name "FQS-I" for its accreditation services

- Provides training and quality systems consultancies
- Board is Ben Perillo (Chairman), Manuel Valadez, Kathy Lee, Art Eisenberg, Sudhir Sinha
- Membership is open to all laboratories accredited through FQS-I and to 2 representatives of the Crime Laboratory community
- Is recognized by NACLA for ISO 17025 accreditation with the scope of forensic science
- The only NACLA-recognized AB with a scope of forensic science
- Has an MoU with SCC

Recognition

- From the very beginning we have been committed to the concept of recognition
- Outside review of conformance to appropriate standards is an integral part of the value of accreditation, and the same applies to the Accreditation Bodies
- We chose recognition through NACLA as the way to provide independent confirmation of the quality of our ISO accreditations
- FQS is also recognized by NIJ and the NDIS board in terms of the Justice for All Act

_ Key Points

- The Standards
 - ISO 17025
 - ILAC G19
 - National QA Standards for DNA Testing
 - The laboratory's own Quality System requirements
 - Any other agreed standards
- The Process
 - FQS operates a process that complies with NACLA requirements and ILAC guidelines

Over 60 years of forensic testing experience and over 30 years of forensic laboratory management experience

- Kevin Lothridge, Executive Director
- Dr. Bill Tilstone, Deputy Executive Director
- David Epstein, Chief Scientist

- 22,000 square foot building is leased at the Young-Rainey Star Center in Largo, FL.
 - Includes a training laboratory

Programs funded through Cooperative Agreements with the National Institute of Justice (NIJ) and the Environmental Protection Agency

Fire Debris Validation Kit

- Partnered with Technical Working Group for Fire and Explosions (TWGFEX) and the National Center for Forensic Science (NCFS) in Orlando, FL to produce a set of instructions and flammable liquids for use by a laboratory in the validation of fire debris analysis
- Referee testing in progress (September December 2005); shipped in Spring 2006

Program Highlights (cont.)

Quality Documents

- Created by the NFSTC and a group of quality managers
- Easy-to-use Quality Manual Template and over 90 document samples designed as a guideline for crime laboratories in the creation of customized quality documents
- Developed to meet the laboratory's needs to ensure a comprehensive quality system

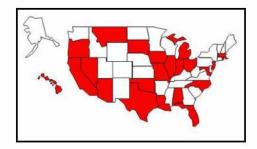

Posted to http://www.NFSTC.org/qualDocs.htm

Program Highlights (cont.)

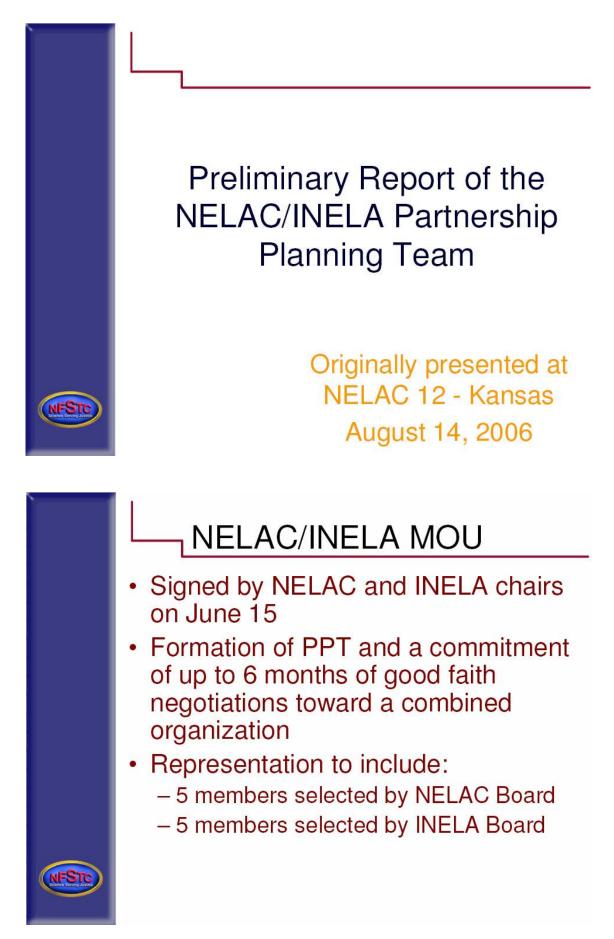

DNA Audit Program

- Provides no-cost, biannual external DNA Laboratory Audits to public crime laboratories performing DNA analysis
- Conducted 149 audits since program inception (total of 166 by end of 2004)

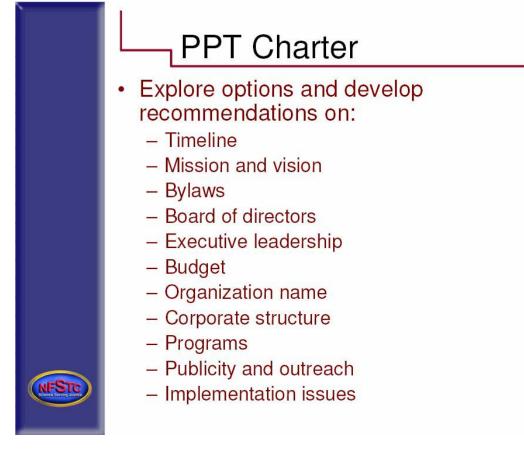

Labs in states that have received or are scheduled to receive audits in 2004 are marked in red.

Underlying Assumptions

- Combining the operations of NELAC and INELA will result in a stronger organization
- Combining operations will allow NELAC to achieve self-sufficiency quicker
- Combining operations is less disruptive to the stakeholder community

NELAC Assets

- Vision for a national accreditation program
- Established infrastructure for recognition of accrediting authorities and accrediting laboratories
- PT Program
- Dedicated volunteer group of state and federal officials
- Cooperative agreement funding through NFSTC to provide support for NELAC/NELAP

Activities of PPT

- Preliminary proposal presented today for discussion and comment
- Addresses 11 key elements

7 Core Values

- 1. Inclusive
- 2. Integrity/honesty
 - No conflict of interest

3. Quality

- Belief that the program is worthwhile
- Quality is an underlying value for everything we do

- 4. Responsive
 - Visionary
 - Proactive
 - Progressive
 - Respect for diversity/balance
 - Flexible
 - Multi-faceted

1141

7 Core Values

5. Open/transparent • 7. Legally defensible

- Information is available
- The process is visible
- Legitimate
- e Credible

6. Self-sustaining

- Partnership
- Independence

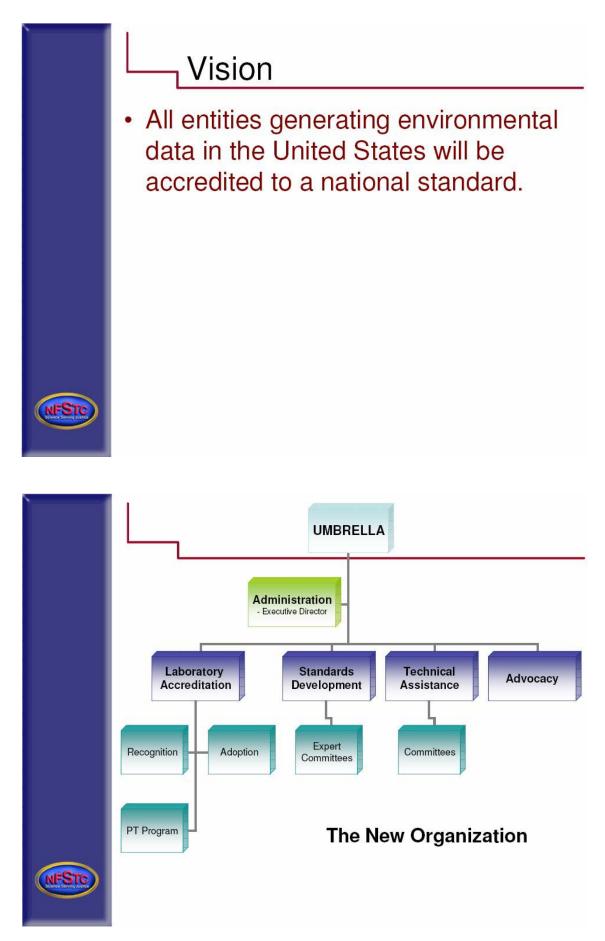

Additional thoughts

- True national program
- Professionalism
- Program
 - Flexibility
 - Quality
 - Strive for consistency

Mission

 The purpose of the organization is to foster the generation of environmental data of known and documented quality through an open, inclusive and transparent process that is responsive to the needs of the community.

Key Programs

- Accreditation of Testing Laboratories
- Development of consensus standards
- Technical Assistance
- Advocacy
- Administration

Accreditation Program

- Standards Adoption
- Credible Recognition of AAs
- Recognition and oversight of PT providers
- Implementation and decision-making limited to government
- Additional input needed on structure and functions of this group

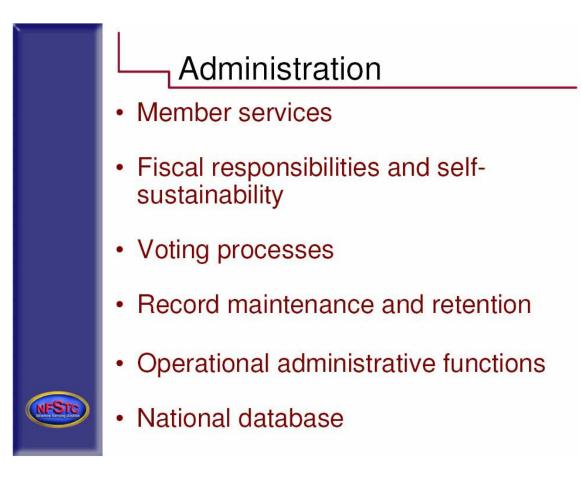

- Consensus process with inclusion of all
- Use INELA model and policies

Technical Assistance

- Outreach
 - Newsletter
 - Presentations
 - Participation at conferences
- Training
 - Laboratories
 - Assessors
 - Evaluators (of AAs)
- Mentoring

- Templates and tools
- Website
- Forum
 - Annual meeting
 - Other mechanisms to foster discussion and information exchange

Advocacy EPA program office acceptance/participation Laboratory participation State participation Other Federal (non-EPA) participation Users of laboratory data Generating documents to support advocacy

Corporate Structure

- Incorporated 501(c)3, not-for-profit
- Member organization
- · Managed by a Board of Directors

Members

- Individual members
 - may vote
 - may serve on committees and the board
 - entitled to member discounts
 - access to members area of website
- Organizational members
 - may appoint individual members
 - are recognized
 - may not vote

Restricted Membership

 Additional membership requirements may be needed for specific programs, e.g. Accreditation Program

- Transition board will be combination of existing boards of NELAC and INELA, 9 members from each board
- New board elected as soon as possible

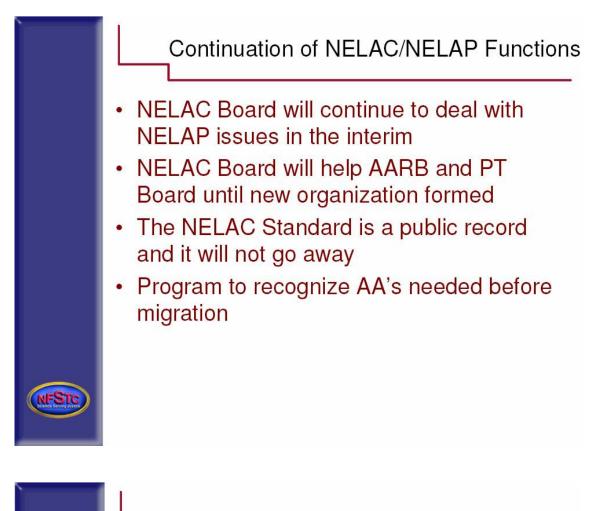

- Executive Director to manage administrative activities of organization under direction of the Board
- Program Directors to manage each key program
 - May be hired staff, contractor, or volunteer
- Support staff for other functions
 - Web site, clerical, meetings, etc.

 NELAA – National Environmental Laboratory Accreditation Association

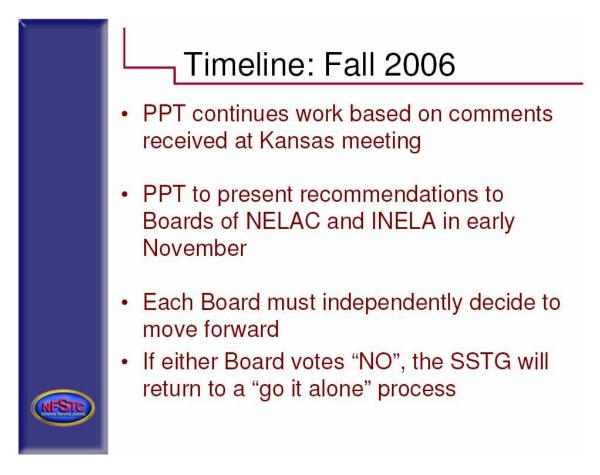

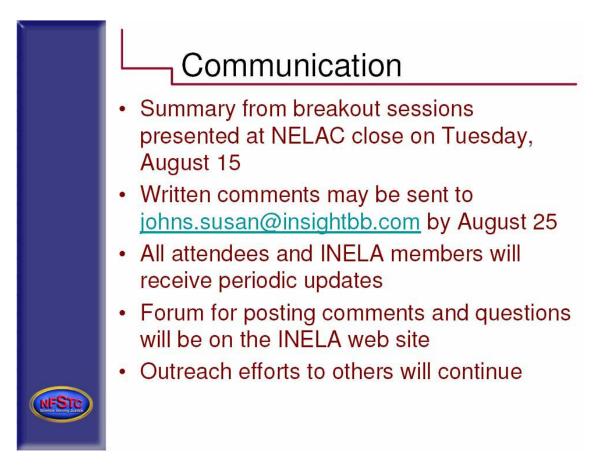

- INELA Board, staff and committees will continue current functions until the new organization begins operation
- Plans to migrate essential assets into the new organization will occur in late Fall 2006, after a decision is reached

Timeline: 2007

- January 2007
 - Organization will have defined members
 - Organization will be operational
 - Transition board will be functional
 - Plan for election of new board announced in Denver

Breakout Sessions

- Your opportunity to review and comment on preliminary proposal
- Discussion topics focused on:
 - Organization and membership
 - Governance and structure
- Additional comments may be submitted up to August 25

Breakout Feedback

- Accreditation
 - ISO
 - Stability
 - Consistency
 - Mutual recognition
 - Dispute resolution
 - Regulatory issues
 - Develop programs to meet a wider customer base (e.g., for non-water)

- Standards Development
 - Is standards adoption necessary or can standards development stand alone?
- Technical Assistance
 - Standardized training for assessors
- Advocacy
 - Need to educate what accreditation means
 - Outreach to EPA Programs and States

Breakout Feedback

- Broad participation vs. State acceptance
- Conflict of interest
- Identify limitations (if any) for government personnel
- Ensure balance
- Tap into unused resources

Breakout Feedback

- Legal advice needed for corporate issues
- NCCLS model
 - Organizations are members
 - Each organization has one vote
- Baseball commissioner model
 - Umbrella board will give the Director real power

Breakout Feedback

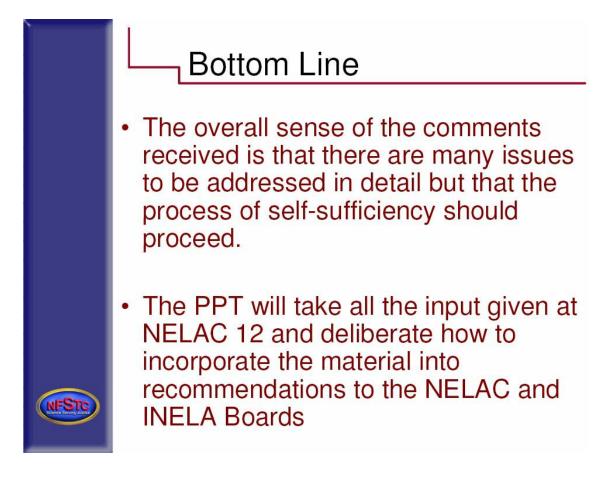

- Board composition
- The interest groups need to be well defined
- Adequate representation by nongovernmental entities

Breakout Feedback Transition Issues

- Ensure continuation of NELAP programs
 during transition
 - Laboratory accreditations by AAs
 - Recognition of AAs and related activities
- Change policies relating to the executive director
- Access historical NELAC and NELAP records
- Advocacy
- Name
- Time is needed to address the issues related to a name change

Addition to Transition Plan

The NELAC Board of Directors recognizes that NELAP AAs and Laboratories will need time to implement changes and proposes a 2 year transition period of the use of the NELAC/NELAP name to give states and laboratories enough time to make these changes.

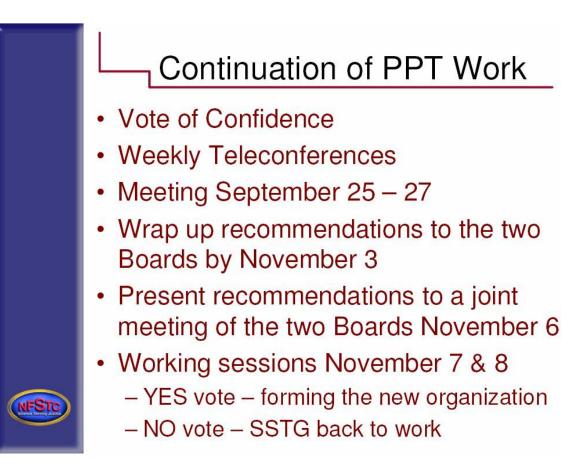

This NELAC conference expresses confidence in the NELAC Board of Directors for the Transition Plan.

Continuation of PPT Work

The NELAC conference expresses confidence in the NELAC Board of Directors for the PPT to move forward with their work for the formation of a new organization.

WEDNESDAY P.M., AUGUST 30, 2006

CONCURRENT SESSIONS

Perchlorate

ANALYSIS OF PERCHLORATE IN DRINKING WATER

Munch, D.J.; U.S. Environmental Protection Agency Pepich, Barry V.; Shaw Environmental, Inc.

Four U.S. Environmental Protection Agency (EPA) methods have been published for the analysis of perchlorate in drinking water. A fifth, which employs Dionex's new 2-D technology, is being validated and should be published shortly. The first method, EPA Method 314.0 supports a minimum reporting level (MRL) of 4.0 μ g/L and was used during the first Unregulated Contaminant Monitoring Regulation (UCMR) cycle (2001-2005).

Perchlorate concentrations above 4.0 μ g/L were reported in approximately 4% of the public water systems tested. Based on these data, together with concerns regarding relative source contributions for perchlorate and available health effects data, EPA is considering whether perchlorate should be regulated in drinking water and/or if additional occurrence data needs to be collected at lower concentrations.

To alleviate potential impediments associated with the availability of appropriate analytical methods, EPA's Office of Ground Water and Drinking Water (OGWDW) initiated method development projects that were aimed at developing new perchlorate methods that offer improved sensitivity, selectivity and method robustness. A central goal was also to take full advantage of the available instrument base in the drinking water community, thereby offering the analytical laboratories the greatest flexibility in method selection. The new methods employ both ion chromatographic (IC) and liquid chromatographic (LC) separation, and detect perchlorate using either conductivity or mass spectrometric techniques.

This paper describes all four OGWDW methods for the analysis of perchlorate in drinking water, specifically Methods 314.0, 314.1, 331.0 and 332.0, and introduces the fifth 2-D method. The most significant challenge remaining in the area of perchlorate analysis may be deciding which method to use.

A Review of the USEPA Methods for the Analysis of Perchlorate in Drinking Water

Barry V. Pepich¹ and David J. Munch²

¹Shaw Environmental, Inc., 26 West Martin Luther King Drive, Cincinnati, OH 45219

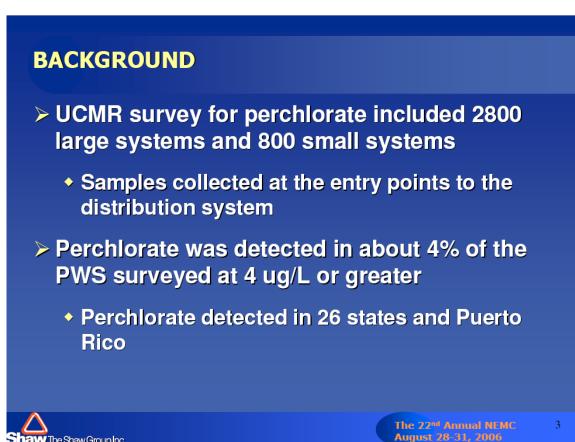

²U.S. EPA, Office of Ground Water and Drinking Water Technical Support Center, 26 West Martin Luther King Drive, Cincinnati, OH 45219

> The 22nd Annual NEMC August 28-31, 2006

BACKGROUND

he Shaw Group Inc

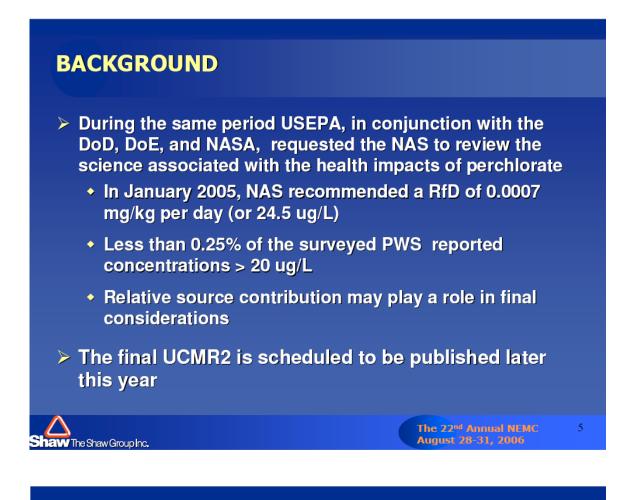

- Perchlorate is an oxidant used primarily in the manufacture of solid propellants. It inhibits the uptake of iodine by the thyroid gland affecting thyroid hormone production
- Perchlorate was added to the Contaminant Candidate List in 1998 but was listed as "reserved" in List 1 of the proposed UCMR (4/1999)
- Perchlorate was added to List 1 in the final UCMR (9/1999) following publication of EPA Method 314.0

BACKGROUND

aw The Shaw Group Inc.

- USEPA completed a Toxicological Review and Risk Characterization for perchlorate in 2002
 - Proposed oral reference dose (RfD) was 0.00003 mg/kg per day or 1 ug/L (for 70 kg adult consuming 2 L water per day)
- OGWDW sought additional methods with improved sensitivity and selectivity that could potentially be used in UCMR2
 - Method 314.0 and 3 new EPA methods were proposed under UCMR2 in August 2005

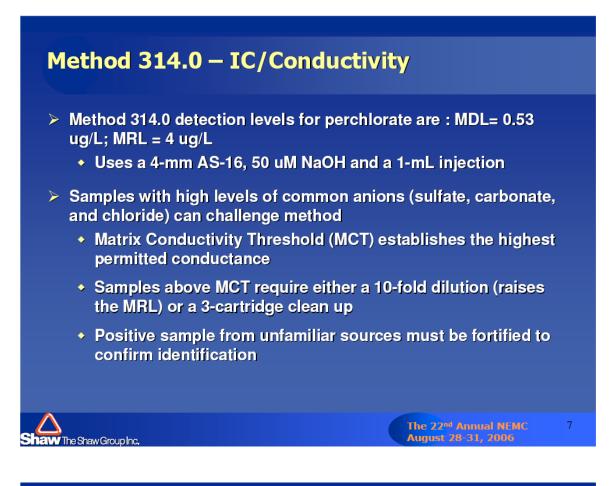

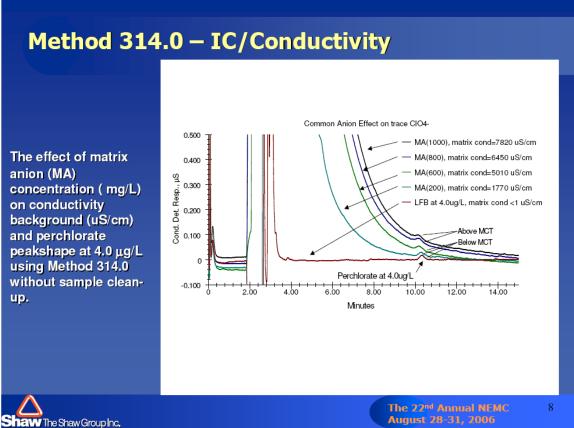

OUTLINE

- Method for UCMR1
 - Method 314.0 IC/Conductivity (D. Hautman)
- Methods for UCMR2
 - Common requirements: sample preservation and LCMRL
 - Method 314.1 IC/Conductivity with column concentration & matrix elimination (H. Wagner)
 - 2-D Method for perchlorate (Dionex lead, Method 314.2)
 - Method 331.0 LC/MS or LC/MS/MS (S. Wendelken)
 - Method 332.0 IC/MS or IC/MS/MS (E. Hedrick)

Shaw The Shaw Group Inc.

The 22nd Annual NEMC August 28-31, 2006

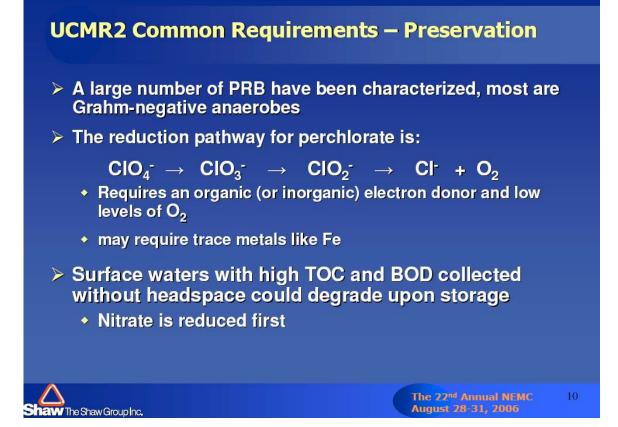

UCMR2 Common Requirements – Preservation

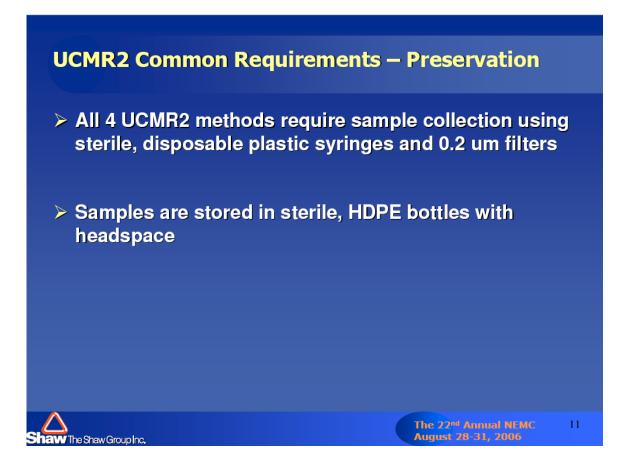

- Perchlorate can be readily degraded by perchlorate respiring bacteria (PRB)
- Shaw bioreactor in Henderson, NV is currently remediating water that feeds Lake Mead using PRB
 - Influent 250 mg/L
 - Effluent < 4 mg/L</p>

N The Shaw Group Inc

- 1,000 gal/min throughput
- Removing about 1 kg/min

UCMR2 Common Requirements – Lowest Concentration Minimum Reporting Level

- The lowest concentration minimum reporting level (LCMRL) is the lowest true concentration for which future recovery is predicted to fall, with high confidence (99%), between 50 and 150% recovery
- Developed by OGWDW after thorough evaluation of literature
- Simultaneously considers precision and accuracy
- Performed during method development (only) and requires 7 replicates at 4 concentrations
- The MRL is confirmed using a simple technique (7 samples at 1 concentration) by labs using the methods – NO ITERATION

Shaw The Shaw Group Inc.

The 22nd Annual NEMC August 28-31, 2006

Published as an EPA document and in ES & T:

CONCLUSIONS

aW The Shaw Group Inc.

- Method 314.0 met EPA's UCMR1 objectives and helped characterize perchlorate occurrence in PWS
- Three additional methods have been developed that have from 10 to 100 times more sensitivity, offer analyte confirmation, and can analyze relatively high TDS samples without additional sample clean-up
- The most difficult task remaining may be choosing which method to use

New EPA Office of Solid Waste SW 846 Methods for the Analysis of Perchlorate in Various Environmental Matrices

Shen-yi Yang¹ and Sharon M. Drop²

¹U.S. EPA Office of Solid Waste; ² Science Applications International Corporation

ABSTRACT

Perchlorate is a high profile non-regulated contaminant and is being detected in many soils, aquifers, vegetables, cow milk, beers and wines in the United States (U.S.). The existing SW-846 method for perchlorate in soil has several limitations. The EPA Office of Solid Waste (OSW) is now developing two new improved methods to provide better quantitative and qualitative capabilities for the analysis of perchlorate in various environmental media. These new methods will be used for perchlorate monitoring and cleanup activities. This paper introduces the two new SW 846 methods under development for perchlorate, and reports the results of a round robin validation study involving multiple laboratories and a variety of environmental media.

INTRODUCTION

Perchlorate (ClO₄) is a both natural occurring and man-made material. Most of the perchlorate manufactured in the U.S. is being used as a primary ingredient of solid rocket propellant, missiles, and fireworks. Wastes from the manufacture and improper disposal of perchlorate containing chemicals are being increasingly detected in various environmental media. Perchlorate inhibits the uptake of iodine by thyroid gland, thus affects thyroid hormone production and thyroid regulation of metabolism; impairs neurological development of fetus and newborn; and changes in thyroid hormone levels may result in thyroid gland tumors¹.

Perchlorate contamination has been detected in various soils, aquifers, crops, milk and beers in Puerto Rico and in 35 states of the U.S. Perchlorate is very mobile in aqueous systems and it is persistent under typical ground water and surface water conditions. Perchlorate absorbs weakly to most soil minerals and it may degrade in certain environmental conditions². The rate of perchlorate degradation depends on the presence of perchlorate reducing bacteria (PRB) and the environment that favors the growth of PRB (e.g., anaerobic conditions, carbon sources, presence of particular nutrients)³.

Previously published methods for perchlorate (including Method 9058 for perchlorate in solids), based on ion chromatography (IC) separation and conductivity detection, are not capable of confirming the presence of perchlorate due to chromatographic interferences^{4,5}. In addition, the existing Method 9058 has no written procedure for extracting perchlorate from solids. OSW is now developing two new improved methods to provide better quantitative and qualitative capabilities for perchlorate in soil, sludge, wastewater and high salt water. The two new methods determine perchlorate using (HPLC, Method 6850; IC, Method 6860) chromatographic separation followed by negative electrospray ionization (ESI) mass spectrometry (MS). Perchlorate is separated (by HPLC or IC) from the sample matrix, partially fragmented via negative electrospray ionization and detected by MS (with in-source fragmentation) or MS/MS using mass-to-charge (m/z) ratios 83, 85 and 89. Quantitation is performed using m/z 83 and

internal standard calibration. Isotopically-labeled perchlorate, (Cl¹⁸O₄), m/z 89, serves as the internal standard. The 83/85 isotopic ratio reflects the isotopic ratio of naturally occurring ³⁵Cl/³⁷Cl and is used for additional confirmation of perchlorate identification. In the absence of interferences a single stage mass spectrometer may be used. In that case the perchlorate is detected and quantified using m/z 99, 101 and 107.

The EPA OSW Perchlorate Task Force, lead by OSW, includes members from EPA Office of Research and Development (ORD), EPA Regional Laboratories, Department of Defense (DOD), instrument vendors and commercial laboratories. The OSW Perchlorate Task Force has provided tremendous support in reviewing/validating these two methods. The Phase I initial demonstration of proficiency (IDP) study was completed in September 2005 and the Phase II methods validation study was completed in July 2006. Information and data collected from our studies are being evaluated and statistically analyzed.

EXPERIMENTAL PROCEDURE

Our validation study was carried out in two phases. Phase I was conducted as an initial demonstration of proficiency (IDP) to identify candidate analytical procedures as well as capable volunteer laboratories for carrying out the actual Phase II method validation. Each of the two developmental methods contains only one analytical system, HPLC/MS for Method 6850 and IC/MS/MS for Method 6860, respectively. In accordance with the Agency's Methods Innovation Rule and in keeping with the original intention of SW-846 Methods as guidance methods⁶, a wide range of HPLC and IC columns, single and dual MS systems, and their respective analytical conditions are being evaluated for inclusion in Methods 6850 and 6860 via large-scale, multi-laboratory round robin studies. Our validation study was devised to compare several different analytical systems and identify those capable of accurately determining perchlorate in a variety of real world matrices. Examples of technologies evaluated in this study are shown in Table 1.

Method	Column	Mobile Phase	Detection	Quantitation Ions (m/z)
6850	K'(Prime) RP	 10 M CH₃CN 35 mM CH₃COOH 	LC/MS	83, 85, 89
	IC Pak™ Anion/HR	 25 mM NH₄HCO₃ 50% CH₃CN NH₄OH (pH 10) 	LC/MS/MS	83, 85, 89
	2 Alltech GA-1 guard cartridges in series	• 0.8 mM CH ₃ CO ₂ NH ₄ • 20% CH ₃ OH	LC/MS/MS	83, 85, 89
6860	MetroSep ASUPP 5	• 30 mM NaOH • 30% CH ₃ OH	IC/MS	99, 101, 107
	IonPac® AS16	• 45 mM KOH	IC/MS	99, 101, 107
	IonPac [®] AS16	• 45 mM KOH	IC/MS/MS	83, 85, 89

Table 1:	Examples of Technologies Evaluated in the Validation Study
	for Methods 6850 & 6850

Phase I: Initial Demonstration of Proficiency

Twenty four laboratories participated in the Phase I IDP study involving two spiked reagent waters. Each reagent water was initially prepared as a single sample, which was subdivided into individual aliquots and shipped to the respective participating laboratories. Laboratories were instructed to analyze daily replicates of each IDP solution over the course of 3 days. In addition to evaluating analytical precision and bias, the capability to accurately determine perchlorate in the presence of a high conductivity background, relative to drinking water, was also assessed.

Phase II: Method Validation Study on Real World Matrices

Twenty laboratories participated in the Phase II study. The Phase II study consisted of a blind, multi-laboratory round robin study involving real world matrices, including soil, sludge and high salt water (synthetic sea water). Each matrix was spiked at 3, 3 and 2 different perchlorate levels, respectively, for a total of 8 samples. The conductivities of samples ranged from $240 - 45,000 \mu$ S/cm. For solids, the matrix conductivity was based on the 1 g/10 mL extract solution. All laboratories were instructed to adhere to the extraction procedure included in the developmental Methods 6850 and 6860 for solid samples. Several laboratories employed the analytical systems described in the developmental methods. Laboratories that have different analytical systems were free to follow their established standard operating procedures for the study. Additionally, a municipal wastewater was collected and spiked at 2 different perchlorate levels and analyzed by a single laboratory in a non-blind study. The Phase II study evaluated: 1) analytical bias and precision between sample replicates and over time (week-to-week); 2) the efficacy of the extraction procedure for perchlorate in solids; 3) a blind single laboratory holding time (HT) study for high salt water; 4) a non-blind HT study for wastewater; and 5) 0.45 μ m vs. 0.1 μ m filtration for preservation of wastewater samples from biological degradation of perchlorate.

RESULTS AND DISCUSSION

Table 2 summarizes the results of the Phase I study. The study results demonstrate that all laboratories were capable of following the methods and their performance were within acceptable range. All laboratories were allowed to continue in participating in the Phase II study.

			Prec	Bias	
IDP Sol'n	[ClO4] (µg/L)	Conductivity (µS/cm)	Sample-to-Sample RSD (%)	Day-to-Day RSD (%)	Based on Spiked Value (%)
1	1.75	< 0.5	0.4 - 7	0.3 - 37	-21 - 6
2	4.0	10,000 ^a	0.3 - 9	0.4 - 28	-19 - 6

Table 2: EPA OSW Phase I IDP Results for Perchlorate Analysis Using Draft Methods 6850 and 6860

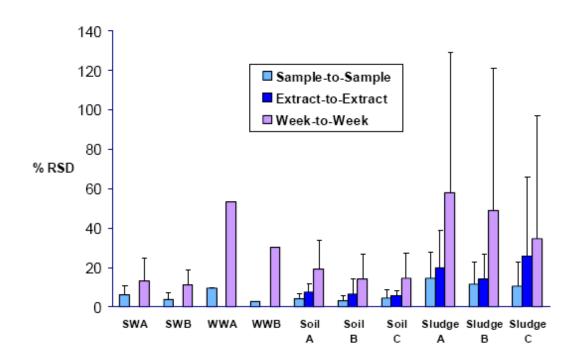

^aThe sample was spiked with 1400 mg/L each of Cl., SO₄, and CO₃² amons.

Figures 2 and 3 present the results of our Phase II study. All laboratories performed well on the salt water and soil samples. Precision between aqueous sample replicates (salt waters and soil extract solutions) replicate soil extractions as well as week-to-week precision for aqueous analytical replicates all averaged less than 20% relative standard deviation (RSD). Similarly, the average bias for the saltwater and soil matrices was less than -40%. These results were

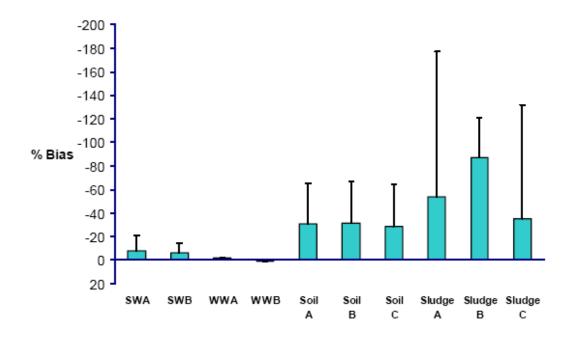

considered to be acceptable, given the complexity and high conductivity of the matrices. The overall trend in negative biases was thought to be indicative of competition for active sites on the chromatographic resin from constituents in the matrices.

Both precision and bias were significantly reduced for the wastewater and sludge matrices. Components of these matrices in some cases, presented deleterious effects to the chromatography, and may have possibly suppressed ionization in the mass spectrometer. We are continuing to investigate the basis for the low recoveries in these matrices. Our studies and those of others suggest that anaerobic perchlorate-reducing bacteria colonies must be established for active perchlorate biological degradation to occur⁷. Thus, perchlorate would be expected to be stable after being spiked into real world samples that did not originally contain perchlorate. The sludge matrix used in the Phase II study was known to originally contain active perchloratereducing bacteria. We are investigating whether favorable conditions may have been present during the time that the sludge matrices were originally spiked, that could possibly have induced degradation of the spiked perchlorate.

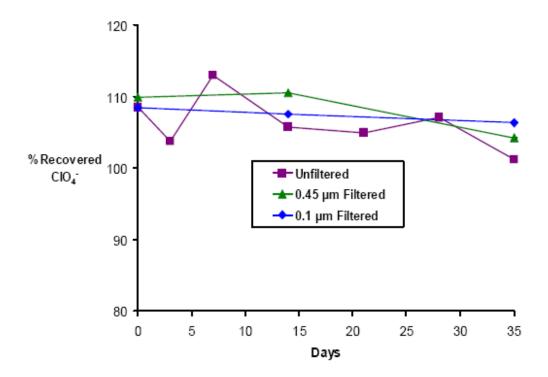

We are also evaluating more rigorous extraction procedures such as the Dionex ASE[®] system which uses elevated temperatures and pressures, the use of alternate extraction solutions, such as 50:50 acetonitrile⁸, and/or cleanup steps in an effort to improve perchlorate recovery in more complicated matrices such as wastewater and sludges.

Figure 4 shows the results of the HT study in salt water indicating that perchlorate does not appreciably degrade in salt water. The results of the wastewater HT study are still under investigation. Previous recommendations for membrane filtration and headspace to minimize microbial growth under anaerobic conditions in aqueous samples appear to be a reasonable approach to deterring biological degradation of perchlorate^{9,10}.

CONCLUSION

Our research has demonstrated the precision, accuracy and applicability of several candidate IC/MS and HPLC/MS technologies capable of providing confirmatory analysis of perchlorate in complex matrices, such as high salt waters and soils. Based on the performances demonstrated in our multi-laboratory method validation, we expect to include a number of analytical systems in the final published versions of Methods 6850/6860 for perchlorate analysis in various environmental matrices. Our investigations into the stability of perchlorate in various samples, have suggested at this time that perchlorate is stable in samples that do not contain perchlorate-reducing microorganisms. However as a precautionary measure, membrane filtration and headspace appear to be prudent practices for preserving aqueous samples. We will continue to evaluate and optimize the sample extraction procedure for more complicated matrices such as waste sludges, through the use of alternate solvents, extraction conditions, and cleanup. From these additional optimization studies, we expect to develop improved recommendations in Methods 6850 and 6860 for extracting and analyzing perchlorate in sludges.

ACKNOWLEDGEMENT

We thank the OSW Perchlorate Task Force for their technical contributions to the development of these methods. We also thank the numerous voluntary laboratory participants for their time, effort and technical input.

DoD PERCHLORATE HANDBOOK

Ingersoll, William S.; NAVSEA 04XQ (LABS) McLean, Fred S.; NAVSEA 04XQ (LABS)

The Department of Defense (DoD) Environmental Data Quality Workgroup (EDQW) prepared the DoD Perchlorate Handbook to assist DoD facilities in complying with current DoD policy governing perchlorate sampling and testing activities for both environmental restoration/cleanup and compliance monitoring programs. Intended users of this document include DoD Remedial Project Managers (RPMs), contractor project managers, and field-sampling personnel. This handbook includes guidance on using conceptual site models (CSMs) to develop project quality objectives (PQOs) associated with sampling and analysis for perchlorate, designing sampling strategies and implementing appropriate sampling techniques. Other topics include selecting qualified analytical laboratories and analytical methods based on required performance objectives and documenting the above in project planning documents in accordance with the Uniform Federal Policy for Quality Assurance Project Plans, March 2005 (UFP-QAPP).

The DoD Perchlorate Handbook was signed out by the Assistant Deputy Under Secretary for Defense, (Environment, Safety and Occupational Health), on May 1 2006.

Data Quality Challenges Ensuring Quality of Information Disseminated to the Public by the Department of Defense (UO1678-03) February 2003

Information must be capable of being substantially reproduced

Data Quality Challenges Emerging Contaminants

- Standards (specific concentrations of concern) do not yet exist
- Laboratories differ in skill, services, equipment, and technology offered
- Methods vary in their ability to detect and recover target analytes
- Analytical methods are not optimized for analyte, matrix, and concentration ranges of interest

Emerging Contaminants Selecting Appropriate Methods

- > Do methods exist that will satisfy your MPCs?
- Is the method suited to your matrix, and concentration range of interest?
- If an existing method does not meet all MPCs, can one be modified?
- Do specific regulatory requirements limit choice of method?

Emerging Contaminants Selecting Qualified Laboratories

- Does the laboratory have appropriate qualifications and credentials?
- Does it offer your selected method?
- Can it document acceptable method performance in the matrix of concern, at the concentration of concern?

Emerging Contaminants Developing Sampling Designs

- Are sample locations and timing appropriate for evaluation of the problem?
- How will you distinguish contaminated media from background?
- Will sample collection and handling procedures protect the integrity of the samples?

Improper method application

- Method 314.0 developed/validated for use in drinking water
- Non-specific/subject to interferences
- > MRL in drinking water = 4 ppb
- Generally not suitable for use in other matrices

Method Description

Analysis of Perchlorate utilizes liquid chromatography to separate Perchlorate from interferences and mass spectrometry to detect, confirm and quantify

Quality Data on Time

Method Detection and Quantitation

✓ Perchlorate at mass 83

Quality Data on Time

Quality Data on Time

Mass spectrometry is used to monitor Perchlorate at mass 83, which is achieved by the partial fragmentation of Perchlorate to remove an oxygen atom. Using mass 83 eliminates known interference caused by sulfate at mass 99.

www.datachem.com

Method Detection and Quantitation

✓ Perchlorate 83/85 Isotopic Ratio

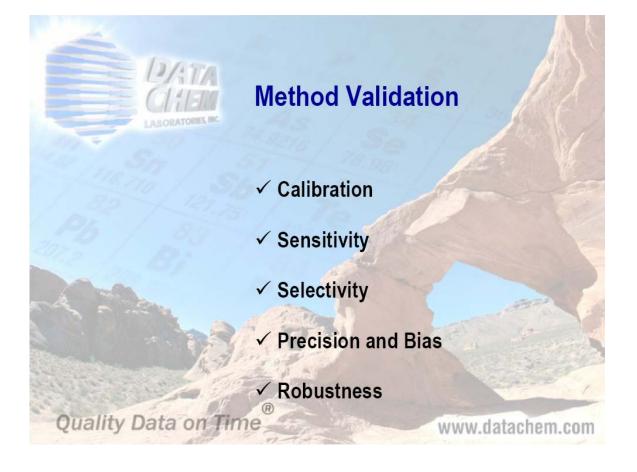

Confirmation of Perchlorate is obtained using the naturally occurring isotopic ratio of ³⁵Cl to ³⁷Cl, which is 3.065, to monitor the ratio of mass 83 and 85 from Perchlorate.

Method Detection and Quantitation

✓ ¹⁸Oxygen Labeled Perchlorate as Internal Standard

Isotopic ¹⁸Oxygen labeled Perchlorate is used as an internal standard and added to each standard and sample. This internal standard is used for relative retention time confirmation, monitoring instrument performance, and internal standard calibration.

Quality Data on Time

Validation study published in Federal Facilities Environmental Journal /Winter 2005 uses multiple concentrations in five matrices analyzed over three consecutive days. The concentrations are at or near the reporting level, at the upper-range of the calibration (upper 20%) and at a mid-range concentration.

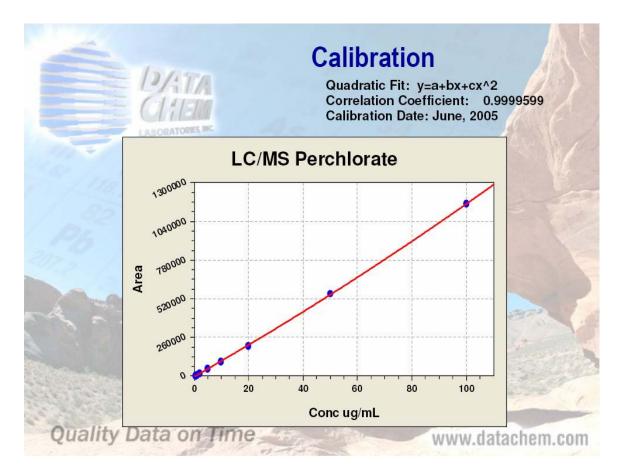

Quality Data on Time

www.datachem.com

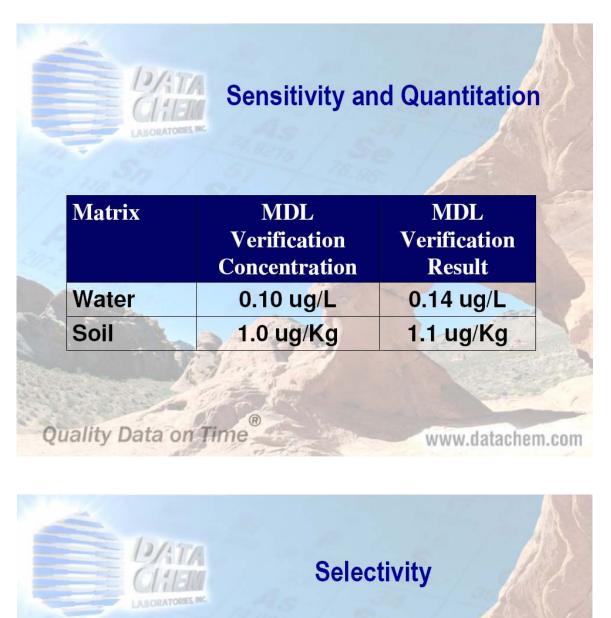

Calibration

A minimum of six calibration standards were used for internal standard calibration. Standard concentrations used to calibrate were 0.2, 0.5, 1.0, 2.0, 5.0, 10.0, 20.0. 50.0, and 100.0 μ g/L. The internal standard of ¹⁸Oxygen Labeled Perchlorate was at 5.0 μ g/L. The standard curve for Perchlorate is established by plotting the ratio for each standard/internal standard area against the concentration.

Modernization of the Superfund Contract Laboratory Program (CLP)

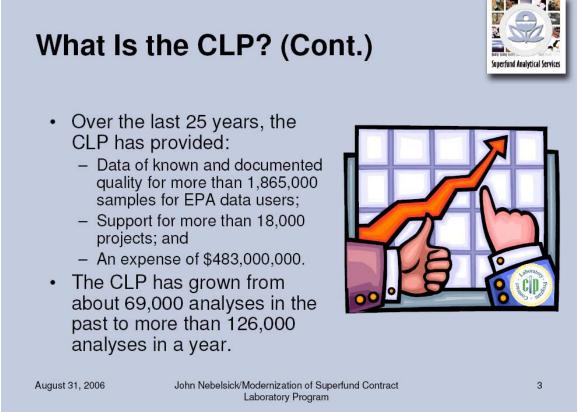

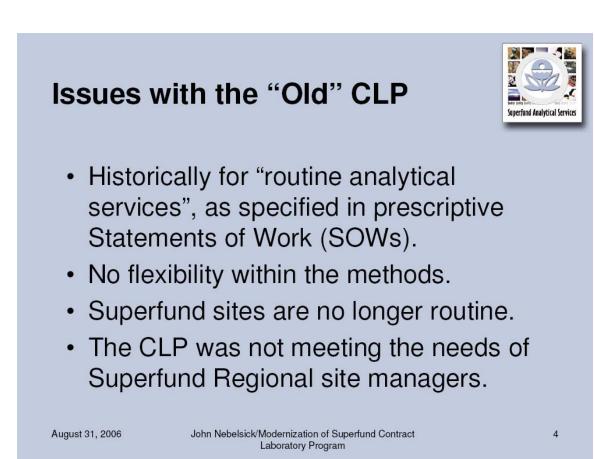

2006 National Environmental Monitoring Conference (NEMC) Presented by John Nebelsick, Inorganic Program Manager

Phil Cocuzza, Organic Program Manager

August 31, 2006

Features of the New CLP

 The CLP provides quick and easy access to a national network of laboratories, available to accept samples 365 days of the year.

 Access begins in the field via the CLP's Field Operations and Records Management System (FORMS II Lite).

August 31, 2006

John Nebelsick/Modernization of Superfund Contract Laboratory Program

Features of the New CLP (Cont.)

- FORMS II Lite allows site samplers to conveniently log completed field sample information, including Geographic Information System (GIS) information.
- Samplers can then generate both hardcopy and electronic Chain-of-Custody Forms, and printed sample labels.

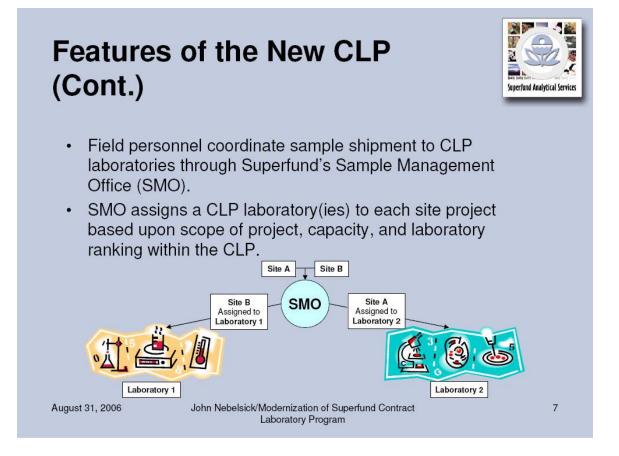

August 31, 2006

John Nebelsick/Modernization of Superfund Contract Laboratory Program

5

- For matching a CLP laboratory with the client's project "scope", the CLP's flexible menu of analytical services provides data users a variety of analyses, data turnarounds, and customized electronic deliverables.
- The CLP's Modified Analysis (MA) option enables users to customize analyte lists, reporting levels, and analytical procedures.

August 31, 2006

9

rfund Analytical Service

- SMO develops laboratory rankings through a process that begins with the monitoring of all laboratory-generated data for timeliness, completeness, adherence to the SOW, and accuracy.
- Up to 4,000 (Organic) and 2,000 (Inorganic) checks are made for each group of laboratory data.

August 31, 2006

John Nebelsick/Modernization of Superfund Contract Laboratory Program

Features of the New CLP (Cont.)

- Laboratory "performance" results are then weight-factored for laboratory price to determine a final laboratory ranking.
- Laboratory rankings are updated on a monthly basis.

August 31, 2006

- Results of the performance monitoring of each set of data is also delivered to the data user within 24-48 hours of delivery of data by the CLP laboratory.
- These results are used for Regional data validation of laboratory data.
- Upon request by the data user, SMO also offers specialized computer-aided data review, formatted to user needs.

August 31, 2006

John Nebelsick/Modernization of Superfund Contract Laboratory Program

Features of the New CLP (Cont.)

- SMO provides further service to Superfund clients by coordinating invoice and payment processes between a CLP laboratory and the EPA Regions.
 - A CLP laboratory submits an invoice to SMO through Superfund's Web-Based Invoicing System (WIS).
 - This invoice is then adjusted by SMO for any financial penalties (for late data, etc.), and then electronically sent to the Regional client for approval.

August 31, 2006

- To complete the full turn-key service provided by the CLP, the Quality Assurance Technical Services (QATS) contractor provides a number of functions:
 - Provides services for annual on-site audits of CLP laboratories;
 - Provides quarterly blind Performance Evaluation (PE) samples to all CLP laboratories;

August 31, 2006

John Nebelsick/Modernization of Superfund Contract Laboratory Program 13

Features of the New CLP (Cont.)

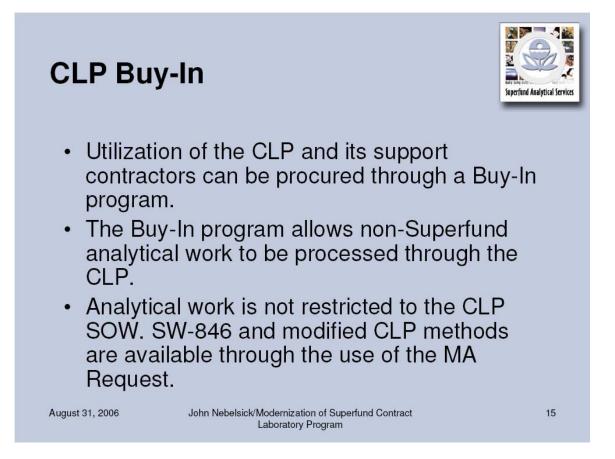

- Provides specialized Regional requested PE samples;
- Provides a complete audit of raw analytical data supplied by CLP laboratories;
- Provides statistical analysis of CLP laboratory results; and

John Nebelsick/Modernization of Superfund Contract Laboratory Program

 CLP staff, Regional technical experts, and support contractors work continuously to provide state-of-the-art and timely analytical services to Regional clients.

Total Inorganic Analyses FY06 (10 Months)

17

	FY06 (10 Months)	Per Month
Routine Analyses	33,183	3,318
Modified Analyses (MAs)	25,980	2,598

- 44% of total analyses are MAs.
- However, if we remove two large projects, then 10% of total analyses are MAs.

August 31, 2006

John Nebelsick/Modernization of Superfund Contract Laboratory Program

Inorganic Laboratory Status **Superfund Analytical Service** Re-Solicited ILM05.3 Contract - Combines Both Inductively Coupled Plasma - Atomic Emission Spectroscopy (ICP-AES) and Inductively Coupled Plasma - Mass Spectrometry (ICP-MS) Capacity Increased to 5,600 Analyses per Month for All Methods Seven Laboratories Are Currently in the Program MAs Available Following A Qualification Phase ٠ August 31, 2006 John Nebelsick/Modernization of Superfund Contract 18 Laboratory Program

Inorganic Future Steps (Cont.)

- Solicit ILM06.X
- Staged Electronic Data Deliverable (SEDD)
- Target a Total Inorganic Capacity of 9,600 Samples per Month for All Methods
- Provide Sufficient Overlap of Contracts

August 31, 2006

John Nebelsick/Modernization of Superfund Contract Laboratory Program

- Include Method Updates:
 - New Approach to Limits of Detection and Limits of Quantitation;
 - Revised Contract Required Quantitation Limits (CRQLs);
 - ICP-MS Soils Analysis;
 - Cyanide Micro-Distillation Preparation;
 - Multi-Point Calibration;
 - Linear Range at Top of Calibration Curve; and
 - Continuing Calibration Verification/ Continuing Calibration Blank (CCV/CCB) Frequency Now Every Two Hours.

August 31, 2006

John Nebelsick/Modernization of Superfund Contract Laboratory Program

19

Total Organic Analyses FY06 (10 Months)

	FY06 (10 Months)	Per Month
Routine Analyses	29,901	2,990
Modified Analyses (MAs)	6,435	644

• 18% of total analyses are MAs.

August 31, 2006

Phil Cocuzza/Modernization of Superfund Contract Laboratory Program

Features of the New Organic (SOM01.1) Method

- New contract combines OLC & OLM methods (soil/water).
- SOW details methods of analyses contemporary to SW-846.
- Incorporates an expanded surrogate list [referenced in the CLP as Deuterated Monitoring Compounds (DMCs)] for Volatiles (VOAs) and Semivolatiles (SVOAs).
- Divides the historical combined Pesticide/Aroclor analytical protocol into separate analyses.

August 31, 2006

Phil Cocuzza/Modernization of Superfund Contract Laboratory Program

Features of the New Organic (SOM01.1) Method (Cont.)

23

- Requires an ending CCV for VOAs and SVOAs analysis.
- Provides options for Low/Medium or Trace-level Volatiles (TVOAs) analysis.
- Provides an option to perform Selected lon Monitoring (SIM) for TVOA and SVOA compounds.

August 31, 2006

Phil Cocuzza/Modernization of Superfund Contract Laboratory Program

Features of the New Organic (SOM01.1) Method (Cont.)

- New requirement to submit electronic data through the SEDD protocol.
- The Data Assessment Tool (DAT) is a software-driven process designed to produce enhanced CLP deliverables and more usable reports in standard format.

• The DAT is flexible and may be adapted to meet unique requirements.

August 31,	2006
------------	------

Phil Cocuzza/Modernization of Superfund Contract Laboratory Program

25

Organic Future Steps

- Re-Solicit SOM01.1. Target a total Organic capacity of 4,000 analyses per month.
- A la carte SOWs [e.g., optional Tentatively Identified Compounds (TICs)]. Use a staged SOW with a supporting SEDD & National Functional Guidelines (NFG) to offer flexible options.
- Stand-alone SIM method for the VOA target compound list.

August 31, 2006

Phil Cocuzza/Modernization of Superfund Contract Laboratory Program

Future CLP

- The Analytical Services Branch (ASB) runs a CLP sister program for Non-Routine Analysis.
- Air analysis by TO-14, TO-15.
- Dioxin by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry (HRGC/HRMS).
- Polychlorinated Biphenyl (PCB) Congeners (all 209) via an analytical protocol developed from the Office of Water Method 1668A.
- The goal is to incorporate these Non-Routine Analyses into CLP use.

Automated Review of Staged Electronic Data Deliverable (SEDD) Stage 3 Deliverables

NEMC 2006 Anand Mudambi, SEDD Program Manager US Environmental Protection Agency August 31, 2006

Contract Laboratory Program (CLP)

- Established in 1980
- Has Processed More than One Million Samples for the US EPA Superfund Program
- Analyses for Metals, Volatile Organics, Semivolatiles, Pesticides, and Polychlorinated Biphenyl (PCB) Aroclors
- Electronic Deliverables Required since Late 1980s

August 31, 2006

Issues with Current CLP Electronic Reporting Format

- CLP has used the Agency Standard Format (ASF) since the early 1990s.
- Inflexibility of ASF has made it difficult to add new analytical methods or Quality Control (QC) requirements.
- Line length limits have imposed strict requirements on field length.
- Nearly impossible to accommodate "non-CLP" data.

August 31, 2006

Automated Review of SEDD Stage 3 Deliverables/Anand R. Mudambi

CLP Interest in SEDD

- ASF Format Not Readily "Human Readable", Therefore Not Suited for Long-Term Storage
- Began Looking for More Flexible Data Formats
- Interest in Formats that "Tagged" Data Rather than Relying on Sequence and Position
- eXtensible Markup Language (XML) and SEDD Meets These Needs

August 31, 2006

Joint Development of SEDD Requirements

- US EPA Office of Superfund Remediation and Technology Innovation (OSRTI) Analytical Services Branch (ASB)
- US Army Corps of Engineers (USACE) HTRW Center of Expertise (CX)
- Input from Other US Government Agencies and the Private Sector

August 31, 2006

Automated Review of SEDD Stage 3 Deliverables/Anand R. Mudambi

Electronic Format Requirements

- Must Clearly Define and Identify Each Data Element
- Must Define Relationships
 within Data
- Must Allow for Change
- Must Not Be Proprietary
- Content Should Be "Human-Readable"

CLP Requirements

- The CLP's need to check calculations from peak areas up to final result.
- The CLP's need to link all analyses to calibration, verification, and preparation and cleanup procedures.
- The CLP's need to clearly and uniquely identify all field and QC samples.

August 31, 2006

Automated Review of SEDD Stage 3 Deliverables/Anand R. Mudambi

The Result – SEDD Stage 3

- SEDD Stage 3 meets the CLP requirements for Format and Content.
- Stage 3 builds on SEDD Stage 2 currently required in US EPA Emergency Response and USACE Contracts.

How Laboratories Produced Stage 3 Files

- Laboratories able to generate compliant deliverables in at least three different ways:
 - use own software and data systems;
 - use external vendor software; or
 - use the SEDD Generator Tool developed for US EPA/ASB.

August 31, 2006

What Is the CLP Doing with the Stage 3 Data?

- Data Is Assessed for Compliance (Complete, Valid, Accurate, Performed as Specified)
- Data Is Qualified Based on National Functional Guidelines (NFG) Document for SOM01.1 (Posted on EPA Website)
- The System is Web-Accessible
- Allows CLP Laboratories to Perform Self-Inspection Prior to Delivery of Data to Government

August 31, 2006

Automated Review of SEDD Stage 3 Deliverables/Anand R. Mudambi

- The CLP EDD is processed through an automated data assessment system that performs two main types of evaluation:
 - Initial Assessment (IA); and
 - Full Assessment (FA).

Automated Review of SEDD Stage 3 Deliverables/Anand R. Mudambi

Initial Assessment

- A subset of SOW requirements that must be complete and correct before the data can be accepted. These requirements include:
 - Data completeness to ensure all data requested by user is delivered;
 - Completeness of EDD to ensure all required data elements and nodes are present; and
 - Conformance of EDD to the DTD, to ensure the EDD structure is correct and usable for Full Assessment purposes.
- The laboratory is notified if the EDD fails IA, and asked to submit a corrected EDD via the Web.

August 31, 2006

Automated Review of SEDD Stage 3 Deliverables/Anand R. Mudambi

- Preformed After a Laboratory Passes IA
- Two Types of Checks:
 - Completeness checks for presence and adherence to all SOW reporting requirements; and
 - Compliance checks to ensure all SOW QC limits are met.
- More than 3,200 Automated QA/QC Checks Performed on Each Deliverable

FA Completeness Checks

- Stage 3 SEDD allows for reporting down to the Peak Level, which includes all data from instrument outputs.
- All required data elements checked for presence and content.
- System-generated defect reports which point out if a required data element is missing or if the value present in it is incorrect.

August 31, 2006

Automated Review of SEDD Stage 3 Deliverables/Anand R. Mudambi

FA Compliance Checks

- Forms the largest portion of the checks.
- All results and values reported by the laboratory in the EDD are recalculated from the instrument data (e.g., integrated peak areas from a pesticide run).
- Accuracy of all reported results verified by recalculation of values starting with the initial calibration curve.

August 31, 2006

FA Checks on Samples

- Contract Holding Time for Extraction
 and Analysis
- Technical Holding Time for Extraction and Analysis
- Verification of results reported for Field and QC Sample Data

August 31, 2006

Automated Review of SEDD Stage 3 Deliverables/Anand R. Mudambi

Examples of FA Recalculations for Pesticides

- Initial Calibration Curve
 - Calibration Factor for Each Standard
 - Mean Calibration Factor for Each 5 Point Calibration
 - % RSD for Each 5 Point Calibration
- Continuing Calibration
 - Relative Percent Difference
- Performance Evaluation Mixture (PEM)
 - Percent Difference
 - Percent Breakdown
- DDT and Endrin Percent Breakdown

August 31, 2006

<section-header><section-header><section-header><section-header><section-header><section-header><section-header><list-item><list-item><list-item><list-item><list-item>

National Functional Guidelines (NFG) Document Checks

- All NFG Calculation checks are performed in FA.
- Results from these NFG checks are used to flag data.
- Generates an overall assessment summary report.

Future System Enhancements

- CLP Developing Modifications to System to Assess Stage 3 Data from Other Programs:
 - Adding Tests;
 - Deleting Tests; and
 - Adding Reference Tables.

Automated Review of SEDD Stage 3

Deliverables/Anand R. Mudambi

August 31, 2006

SEDD CLP Requirements Under Development (Potential)

- Asbestos by TEM
- Isotope Dilution HRGC/HRMS for Dioxins/Furans and PCB Congeners

August 31, 2006

Automated Review of SEDD Stage 3 Deliverables/Anand R. Mudambi

PERFORMING AUTOMATED DATA REVIEW AND DATA QUALITY ASSESSMENT ON SEDD FILES

Denzer, Scott M.; Laboratory Consultants, Inc.

This presentation discusses software applications for viewing and utilizing data transmitted in the Staged Electronic Data Deliverable (SEDD) format. Discussion will focus on parsing data from SEDD files, performing automated data review and mechanisms to move and store data to meet project specific electronic data management goals.

One of the software tools, the Automated Data Review (ADR) software, was developed under contract with the Army Corps of Engineers in order to capture and review data in a timely and cost efficient manner. The ADR software allows laboratories to verify compliance with project-specific data format and content rules and allows data users to evaluate and qualify data based on project specific criteria.

Project-specific data requirements are developed as a library within ADR and electronically transferred to the laboratory. Requirements include specific data quality objectives (i.e., required reporting limits) for each analyte within the various analytical methods for a project. This library is used by the laboratory to ensure the contents of a SEDD file meet project electronic deliverable requirements and is also used by the data user to perform an automated review and qualification of data.

Data movement and storage will also be discussed, including recent developments allowing transfer of reviewed data and ADR project library information in XML format for portability and long term storage.

Staged Electronic Data Deliverable (SEDD) – Overview and Implementation Status

Anand R. Mudambi

US EPA Office of Superfund Remediation and Technology Innovation, Washington, DC 20460

ABSTRACT

The Staged Electronic Data Deliverable (SEDD) is a program neutral format for the delivery of analytical data. It supports multiple requesters' needs depending on the level of reporting requirements as the format clearly reports both simple and complex laboratory processes. The main advantage of SEDD is that laboratories do not have to completely overhaul their Electronic Data Deliverable (EDD) generating systems as data requester needs become more complex, but can simply add additional elements to their current system. Using SEDD as the basis of electronic delivery of analytical data will decrease costs by reducing the number of EDDs laboratories currently have to support and ease data exchange between various programs and agencies.

SEDD files are delivered as XML (eXtensible Markup Language) files. XML is sponsored by the World Wide Web Consortium (W3C) and is a license free, platform independent, final recommended standard. It is well supported by freely available third party tools.

At the present time different Stages for SEDD have been developed based on the complexity of data reporting requirements needed. Valid values for certain key data elements have also been defined.

Delivery of analytical data in the SEDD format is now a requirement for certain Federal Agencies including the U.S. Environmental Protection Agency and the U.S. Army Corps of Engineers. Laboratories are already delivering data using the SEDD format to these agencies under certain programs.

Interagency efforts are underway with the U.S. Navy, U.S. Air Force, some states, and the Department of Energy to promote the use of SEDD.

INTRDUCTION

The Federal Agencies including the US Environmental Protection Agency, US Department of Defense and US Department of Energy collect large amounts of data to make environmental decisions like extent of site contamination, cleanup remedies, and site remediation end points. In order for this information collection to be efficient and cost effective, data collected in electronic formats are the preferred option due the ease of transmission, receipt, evaluation, storage, and retrieval.

Many of the benefits of electronic data are nullified if they are transmitted in proprietary formats since data cannot be exchanged between various groups. This data exchange is very important since many environmental decisions are taken based on data that is collected by one Federal entity and then reviewed by many others.

There is thus a strong Federal need to receive electronic data used for environmental decisions in:

- A non-proprietary open data standard formats like HTML (Hyper Text Markup Language) and XML (eXtensbile Markup Language)
- b. A uniform electronic format especially for environmental data that needs to be exchanged.

OPEN DATA STANDARD – ADVANTAGES AND EXAMPLES

Open data standards have been many significant advantages. They ease data exchange between parties and allow vendors to compete on a level playing field. One big advantage for the Federal Government is that use of open data standards prevents individual monopolies from locking a large market share into their proprietary formats. These standards also are forced to evolve to meet as future needs change and provide incentives for market forces to ensure backward compatibility.

Examples of open data standards are the Hyper Text Markup Language (HTML) used for creating web pages on the Internet and the Extensible Markup Language (XML) which is becoming the standard for data exchange. XML provides a common approach for transmitting information over the Web. This language is a Final Standard recommended by the World Wide Web Consortium (W3C).

THE PROBLEM – TOO MANY ELECTRONIC DATA DELIVERABLES FOR ENVIRONMENTAL LABORATORIES

In today's information age, the environmental laboratories have to report data to most of their clients (including Federal Agencies) in an electronic format. These formats can range from simple electronic spreadsheets to complex ones like the US Air Force Installation Restoration Program Management System (IRPMS) and US EPA's Agency Standard Format (ASF) electronic deliverables. The information conveyed by the electronic data deliverables (EDDs) also varies widely depending on client needs. Laboratories routinely have to support a myriad of reporting formats (in some cases over 100 electronic formats), which increases their operating costs. These formats are also constantly changing as client requirements and methods change adding even more costs to an already burdened industry.

The proprietary nature of many electronic formats also limit the number of laboratories that can be accessed by clients and similarly limit the number of clients that can be accessed by laboratories.

The different types of electronic deliverables also pose problems for the laboratory clients (including Federal and State Agencies), which have to create different electronic tools to evaluate the quality of the data present in the EDDs. It is very expensive to develop and maintain these evaluation tools, which can then be used only for the EDDs for which they were created. Because of the cost of developing the data quality review tools, the electronic deliverable is used mainly for populating client databases, while the data quality review is done manually using the hard copy deliverables. The data in the client database is then changed based on the hard copy

review resulting in a two step process of data entry before the data from the EDD can be used.

Finally with decreasing budgets, it becomes even more vital for Federal Agencies to share electronic information and this becomes difficult (if not impossible) if the EDDs are proprietary.

THE SOLUTION - SEDD

SEDD stands for Staged Electronic Data Deliverable. The SEDD Specification provides a common structure and data element dictionary to report a wide variety of data (chemical, radio chemical, biological, etc.) to multiple customers. The SEDD Specification allows for reporting of analytical data in multiple formats ranging from simple sample concentrations all the way to a CLP type data package and beyond. The SEDD Specification views reporting of analytical data in the same manner as the laboratory produces it - i.e., it is based on the way data is generated in the laboratory for the analysis of a sample. The SEDD Specification is thus designed for reporting the laboratory results to the site specific sample information to be able to connect this laboratory results to the site specific sample information taken during the collection of the sample in the field.

The SEDD Specification consists of the following documents:

- An Overview Guide which gives the specifications and structure of creating a SEDD file. Creating a SEDD file requires the use of XML technology and EDDs created using the SEDD Specification are transmitted as XML documents. XML is an open Data Standard and stands for eXtensible Markup Language. It provides a common approach for transmitting information over the Web. This language is a Final Standard recommended by the World Wide Web Consortium (W3C).
- A Data Element Dictionary that gives the SEDD data elements, their corresponding definitions, and allowed valid values.

The latest versions of these documents are available at the following website: [www.epa.gov/superfund/programs/clp/sedd.htm].

Both the Overview Guide and Data Element Dictionary are agency and program neutral - i.e., they do not contain biases or requirements for any particular agency or program.

WHAT IS A SEDD FILE?

- 1. A SEDD file is a hierarchal electronic file created by a laboratory from their information management system (a single or multiple databases) and is based on the SEDD Specification.
- 2. A SEDD file is a XML document (with an .xml extension).
- The SEDD XML Document contains information regarding the chemical analysis of sample(s).

COMMON SEDD MISCONCEPTIONS

Thus the SEDD XML document is not a database used for generating electronic reporting formats like Laboratory Information Management Systems (LIMS) or used for receiving, storing and retrieving environmental data like the US EPA's STORET (STOrage and RETrieval) and SDWIS (Safe Drinking Water Information System). It is also not a file or a parser.

SEDD STAGES

From the SEDD Specification four (4) specific EDD formats (stages) have been created. These individual formats are unique in that each stage directly builds on the previous stage allowing the user to specify the level of detail as needed for a given program or project. These SEDD stages lay out the reporting requirements for a SEDD electronic data deliverable that is agency and program neutral. Thus it can be used for data exchange between agencies and programs.

Stage 1 only uses a small part of the overall SEDD structure and contains a minimum number of data elements to transmit results only data.

Stage 2 contains all of the Stage 1 structure and data elements but adds additional structural and data elements to report method quality control (Stage 2a) and instrument quality control (Stage 2b) information.

Stage 3 contains all of the Stage 2 structure and data elements but adds additional structural and data elements to allow for the independent recalculation of the reported results (e.g., as required by CLP).

A fifth format (Stage 4) is now under development that would build on Stage 3 and allow for the reporting of all raw instrument data files.

ADVANTAGES OF USING SEDD (INCLUDING COST SAVINGS)

SEDD offers significant advantages to all parties that have to generate, receive, or review analytical data. Use of SEDD will reduce the number of EDDs laboratories have to support as the same EDD format based on SEDD can meet multiple client needs.

Data requesters can build common automated tools to review SEDD files. SEDD files being delivered by laboratories are already being reviewed using electronic tools. Preliminary results show a 30-50% cost savings when compared to the same level of manual review.

Finally SEDD files are XML documents – hence they are non-proprietary and can be used for long term storage of data.

SEDD STATUS AND IMPLEMENTATION

US EPA now requires that all analytical data delivered for the Superfund Technical Assessment and Response Team (START) and Response Action Contracts (RACS) well as the Contract Laboratory Program (CLP) be delivered in the SEDD format. The CLP requires the delivery of a Stage 3 EDD, which will allow for a full independent recalculation of the reported results from raw data. The US Army Corps of Engineers (USACE) now requires the delivery of SEDD files for the FUDS (Formerly Used Defense Sites) Program. USACE contracts are being modified to meet this requirement. Several projects have been competed which successfully parsed these EDDs into various data assessment systems and databases.

SEDD INTER AGENCY EFFORTS AND OUTREACH

US EPA is now also working with other agencies and states to ensure SEDD can meet their requirements. Implementation projects are underway in all 10 US EPA Regions to ensure a smooth transition from the creation of SEDD files by laboratories to electronic evaluation of these files by clients.

SEDD IMPLEMENTATION SUPPORT

US EPA is providing implementation support to all parties interested in using SEDD. The following tools are available for free from the US EPA SEDD Implementation page website: [http://www.epa.gov/superfund/programs/clp/sedd-labs.htm].

- a. The SEDD Generator Tool that assists laboratories in creating SEDD files (SEDD files can also be created using vendor support or in-house systems).
- b. The SEDD Parser Tool that converts SEDD files for review by electronic tools.
- c. A FORM I generator which allows users to view the data results on a hard copy form.

This website also has a SEDD/Automated Data Review (ADR) Project Implementation Overview document which assists personnel who are interested in implementing SEDD along with electronic review tools for their projects.

The following website gives the names of laboratories and vendors supporting SEDD: [http://www.epa.gov/superfund/programs/clp/sedd2.htm]. US EPA can also provide contract language for implementing or requiring to interested parties.

CONCLUSION

The public and private sector can no longer afford to deal with the hundreds of electronic reporting formats from laboratories. SEDD is a versatile format that can meet multiple program and agency reporting requirements. It is now a contract requirement for the delivery of analytical data for some EPA and USACE programs. Using SEDD along with electronic tools can save both time and money in the area of analytical data delivery and review as well as usher in an era of easy data exchange between multiple parties. Please contact Anand R. Mudambi (US EPA) or Joseph Solsky (US Army Corps of Engineers) for more information regarding the SEDD Specification, SEDD Pilot Projects, SEDD Interagency Efforts or development of tools for evaluating and processing EDDs based on the SEDD Specification.

Staged Electronic Data Deliverable (SEDD): Overview and Implementation Status

NEMC 2006 Anand R. Mudambi US Environmental Protection Agency (USEPA) August 31, 2006

Federal Agency Need for Data in Electronic Format

- Collection of Large Amounts of Data Required to Make Various Environmental Decisions, Including:
 - Cleanup Remedies
 - Site Remediation End Points
- Ease of Transmission, Receipt, Evaluation, Storage, and Retrieval
- Efficient and Cost-Effective

August 31, 2006

XML – A Self Defining Data Format

- Final Recommended Standard by the World Wide Web Consortium.
- Each Piece of Data in XML Has a Tag (or Is Tagged) so the Electronic Data Deliverable (EDD) Is Self-Defined.
- Under SEDD, the EDD From the Laboratory Is Transmitted as an XML Document Based on a Document Type Definition (DTD) or a Schema.

August 31, 2006

Staged Electronic Data Deliverable (SEDD) Overview/Anand R. Mudambi

What is SEDD?

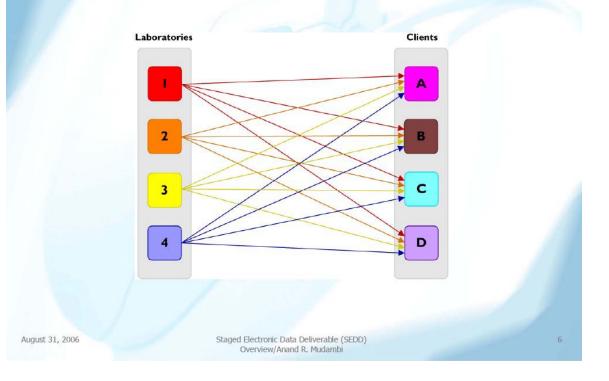

- SEDD is a hierarchal file created by a Laboratory Information Management System (LIMS) or any other database.
- A SEDD file contains information regarding the chemical analysis of sample(s).
- Information (analytical results) from a SEDD file can be reviewed and then input into customer databases using parsing routines.
- Parsing routines need to be written ONLY once for each database type.

August 31, 2006

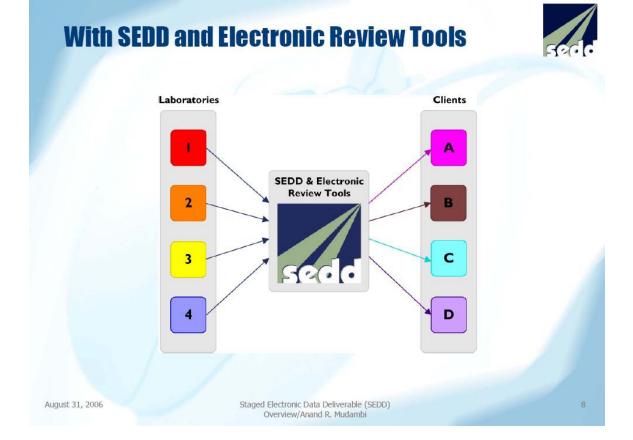

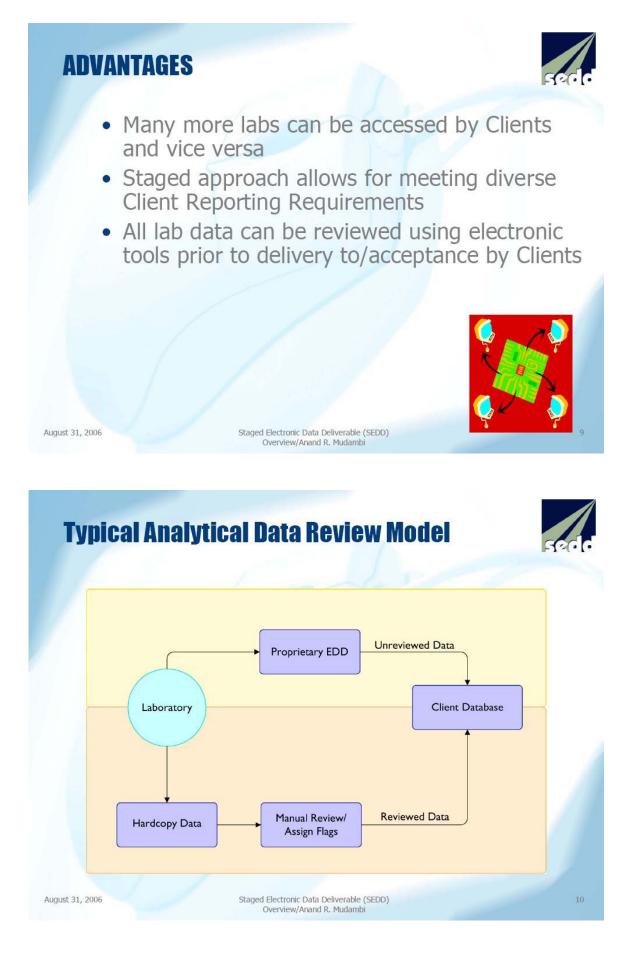

DISADVANTAGES

- Proprietary formats limit the number of labs that can be used by clients and vice versa
- Labs have too many EDDs (up to a 100)
- Labs become focused on their EDD and IT departments instead of sample analysis
- EDDs cannot be readily exchanged between various clients

August 31, 2006

DISADVANTAGES

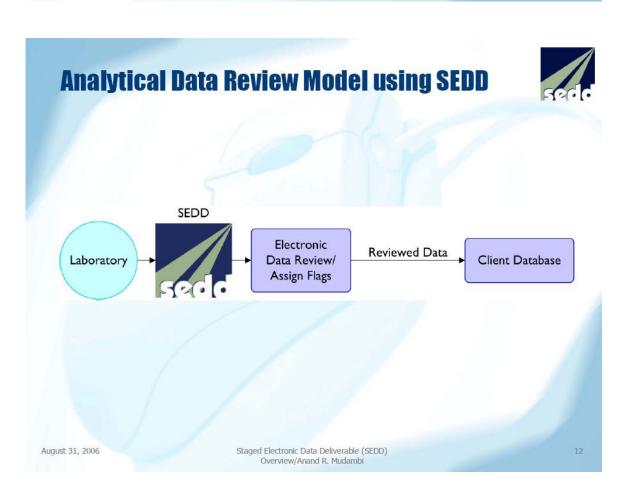

August 31, 2006

- Review of data is mostly done on the hardcopy by the client
- All data cannot be reviewed in a timely manner

Staged Electronic Data Deliverable (SEDD) Overview/Anand R. Mudambi

 Proprietary/program specific EDDs are generally not suitable format for long term data storage or retrieval

ADVANTAGES

- All lab data can be reviewed prior to input into client database using electronic tools (already developed and in development)
- More confidence in the quality of data for the client since 100% of received data is reviewed
- Analytical Data Delivered in XML Format (Non-Proprietary)- suitable for long term storage and later retrieval

August 31, 2006

Staged Electronic Data Deliverable (SEDD) Overview/Anand R. Mudambi

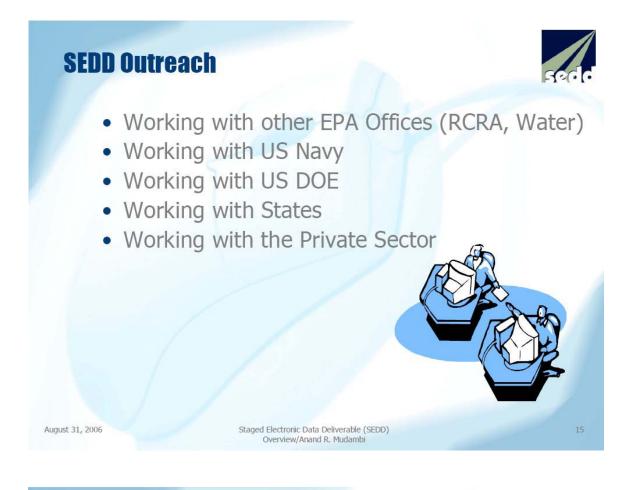

SEDD Status

- Many laboratories (including at least one major network) are already delivering compliant SEDD Stage 2 and Stage 3 files.
- Two LIMS vendors now support SEDD.
- SEDD files are now being input and checked by Automated Data Review (ADR) software (EPA, USACE and other private sector vendors).

August 31, 2006

What's Upcoming with SEDD!

- EPA Website to Allow Generation of Hard Copy Reports from SEDD Files (XSL Style Sheets)

 Completed (See SEDD web page for details)
- EPA Website to Allow Automated Checking of SEDD files for Compliance – In Development

August 31, 2006

SEDD Implementation Support

- For Laboratories, SEDD Generator Tool Provided by US EPA (FREE) to Create SEDD Files
 - SEDD Files Can Also Be Created Using Vendor Support or by In-House Systems
- For Federal Agencies and Contractors Working on Federal Projects, Automated Data Review (ADR) Software Is Available (FREE*)

Staged Electronic Data Deliverable (SEDD) Overview/Anand R. Mudambi

A Technical Overview of the Staged Electronic Data Deliverable (SEDD)

Joseph Solsky

U.S. Army Corps of Engineers (CENWO-HX-C), 12565 W Center Rd, Omaha, NE 68144

ABSTRACT

Due to the various levels of data complexity and reporting required by requesters, it is impossible for one single electronic data deliverable (EDD) format to be able to meet the needs of the multiple data users. The Staged Electronic Data Deliverable (SEDD) solves this problem by reporting data using multiple formats known as 'Stages', with each stage building on the next. Currently, three stages have been defined for SEDD. A common structure has been developed that will allow for the reporting of all types of data. SEDD allows for the complete linking of all samples to their associated QC samples, the complete linking of all samples to their associated continuing and initial calibration data, and the complete linking of all reported results to the specific analysis that was used to derive that specific result.

SEDD delivers data in the form of an XML document. In order to create or use a SEDD file, a Document Type Definition (DTD) or Schema file from the U.S. EPA SEDD website is required. Another problem with current EDDs is the existence of client specified valid values within these EDDs. These valid values can be significantly different to the point where the methods used or the analytes being reported would not be recognizable to anyone other then the original data requester, thus making data exchange between parties difficult. The latest version of SEDD (Draft Version 5.1) addresses this and other issues.

INTRODUCTION

Most commercial laboratories are now delivering data to their customers in both hard copy and electronic formats. More and more emphasis is being placed on these electronic formats and it is not uncommon for an average sized commercial laboratory to deliver data to various clients in over one hundred (100) different electronic formats. This is both time consuming and costly. Most of these electronic formats are customer specific and proprietary and were designed to directly import the reported data into customer-specific databases. The proliferation of these customer-specific and proprietary formats makes it very difficult to share data between customers and develop software to further review and process the reported data.

WHAT IS SEDD?

No one single electronic data deliverable format would be able to meet the needs of the multiple data users due to the various levels of data complexity and reporting as required by those users. Some users require only that the final testing result(s) be reported along with some general sample information. Other users require that the laboratory report summary method Quality Control (QC) data while other users require the reporting of sufficient information to independently recalculate all reported data. As a consequence, SEDD accommodates the reporting of data in 'Stages', with each stage building on the next using XML technology. Currently, three stages or unique electronic data deliverable formats have been defined for SEDD. Stage 1 contains the minimum number of analytical data elements to report 'Results Only'

data to the end user. Stage 2 builds on Stage 1 and adds method (Stage 2a) and instrument (Stage 2b) Quality Control (QC) data. Stage 3 builds on Stage 2 and adds additional measurement data to allow for the independent recalculation of the reported results.

SEDD delivers data in the form of an XML document. XML (eXtensible Mark-up Language) was originally developed by the World Wide Web Consortium (W3C) and was initially published in early 1998. It was designed to ease data exchange between various parties, especially between various databases. Today's databases can readily import and export XML. An Electronic Data Deliverable (EDD) that is based on XML is self-defining since each piece of data is 'tagged'.

A common structure has been developed for SEDD that will allow for the reporting of all types of data. SEDD allows for the complete linking of all samples to their associated QC samples and the complete linking of all samples to their associated continuing and initial calibration data. Various non-target analytes, such as internal standards and surrogates, can be linked to their associated target analytes. All reported results can be linked to the specific analysis or analyses that was used to derive that specific result. SEDD also provides a means for the reporting of complex analytical relationships. For example, the reporting of data can be difficult for the Polychlorinated Biphenyls (PCBs). PCB results can be calculated by establishing separate calibration curves for each peak chosen and averaging the separate calculated peak results together. PCB results can also be calculated by summing up selected or all chromatographic peaks together to establish a single calibration curve and then reporting the final result from this single curve. SEDD does not dictate which specific approach a laboratory must use but can readily capture what the laboratory did and report the results to the data user. SEDD can readily report data that is generated by summing various analytes together, averaging results together from two or more analyses, results that are derived from the Method of Standard Additions and other techniques.

A typical SEDD file is structured as a hierarchial file. An example of what part of a typical file might look like follows:

<ReportedResult> <AnalyteName>Benzene</AnalyteName> <CASRegistryNumber>71-43-2</CASRegistryNumber> <Result>24.2</Result> <ResultUnits>ug/L</ResultUnits> </ReportedResult>

The above file is described as 'self-defining' since all of the reported data is identified with 'tags'. For example, the data element 'AnalyteName' is located within the 'ReportedResult' node and contains the value 'Benzene'. Each reported value is preceded and followed by an associated data element name 'tag'. Nodes are simply data elements that contain other data elements instead of specific values. Typical SEDD files can become rather large. These files can be easily viewed and edited using commercial software. One such Freeware product is XML Notepad. XML Notepad is a Microsoft product that is no longer supported or available from Microsoft, however, it is still freely available over the internet.

In order to create or use a SEDD file, an associated Document Type Definition (DTD) file would be required. For each Stage of SEDD, the DTD would specify what parts (nodes) of the overall SEDD structure would be required and what specific data elements would be available for use within each part (node) of the SEDD structure. Thus, a DTD can be used to 'validate' a SEDD file to ensure that it meets the structural requirements as specified in the corresponding DTD. Currently, generic DTDs have been developed for Stages 1, 2a, 2b and 3 of SEDD. Recently, DTDs are being replaced by Schemas. Schemas are similar to DTDs but offer additional content checking and validation features. Schemas will soon be adopted for use with SEDD in the near future.

In addition to the multitudes of noncompatible EDDs that currently exist, another significant issue that exists are the client specified values that are contained within these EDDs. These 'valid values' can also be significantly different to the point where the methods used or the analytes being reported would not be recognizable to anyone other than the original data user. The latest version of SEDD (Draft Version 5.1) addresses this problem. For the data elements that identify the methods used or the analytes reported, SEDD uses three tiers of data elements. Methods and analytes are identified at the laboratory level, at the client level and at a national reference level. SEDD will not prescribe valid values at the laboratory or client level but will require them at the national reference level. The SEDD valid values not only report the valid value but the reference from which the valid value was derived. By reporting data in this manner, the data can now be recognized by multiple clients. Many of the data elements within SEDD use valid values that can be directly referenced to nationally or internationally recognized sources.

SEDD STAGE 3 FILES AND BEYOND

A SEDD Stage 3 file captures and reports all of the data needed to independently recalculate all final results by capturing this data in the manner in which in was generated. By capturing the data in this manner, the data can be reported and reviewed against the requirements of many different programs. For initial calibrations, average calibration/relative-response factors, linear regressions, quadratic regressions, and other techniques can all be used. These calibration strategies can be applied on a per peak basis or applied when peaks are summed together. Various weighting factors can also be used when regressions are performed. In addition, either 'external standard' or 'internal standard' procedures can be used for any analyte using any method. This same type of flexibility that is used for the reporting of initial calibrations is used throughout the sample preparation and analysis process.

This independent recalculation is performed by starting with an integrated area count for a typical organic chromatographic method or by starting with a background corrected spectral intensity measurement for a typical inorganic spectroscopic method. Data for each standard used is captured. This would include the standard's concentration and amount used, its identification, and the original vendor and lot number of the standard. Each step of the sample preparation, sample cleanup and sample analysis is captured such that the entire analytical process can be recreated.

At the present time, a SEDD Stage 3 file cannot deliver raw instrument data, such as chromatograms, or other laboratory documents, such as Chain-of-Custody forms. Due to the

proprietary nature of most instrument raw data files, the storage and long term archiving of this data has become a problem. Laboratories must often save older copies of software and/or instrument hardware to access these files. As these older systems age or when laboratories close, this raw data is often lost forever.

A SEDD Stage 4 file would have the identical structure as a SEDD Stage 3 file except that it now contains all of the instrument raw data. To address the items that were mentioned in the previous paragraph, a stage 4 file would store the data in an XML format. ASTM (American Standard for Testing and Materials) Subcommittee E13.15 is currently developing the requirements for the storage of raw instrument data files in an XML format called AnIML (Analytical Information Markup Language). More information can be obtained on AnIML at their website (http://animl.sourceforge.net/). The SEDD Stage 4 has not yet been developed, however, information interchange is now taking place between EPA and this ASTM group.

In addition, SEDD is expected to grow to include other areas, such as reporting of data for the radiochemical methods, reporting of field geological data, reporting of overall project data. Once a standardized EDD format is accepted, private vendors can now develop additional software to review, assess, and validate the data.

CONCLUSIONS

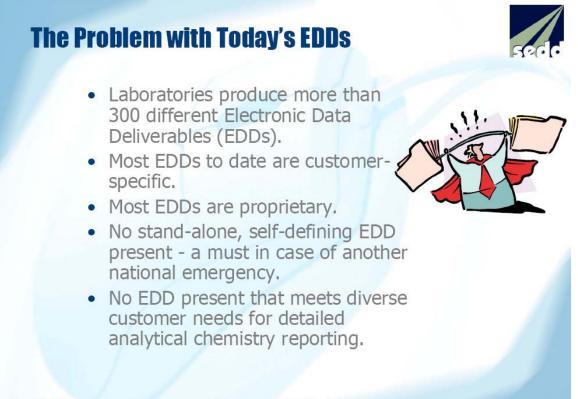

SEDD has the potential to replace many of the client-specific proprietary Electronic Data Deliverable formats that are in current use throughout the environmental testing and other industries. Several programs with the Environmental Protection Agency (EPA), notably the Contract Laboratory Program (CLP), and within the Department of Defense, notably the Formerly Used Defense Sites (FUDS) program as implemented by the U.S. Army Corps of Engineers, now require the use of SEDD. More than two dozen testing laboratories now have the capability to generate SEDD files. In addition, two LIMS vendors now have the capability of exporting data in the SEDD format. Additional information on SEDD can be found at the following web site: www.epa.gov/superfund/programs/clp/sedd.htm.

A Technical Overview of Staged Electronic Data Deliverable (SEDD)

NEMC 2006 Joseph F. Solsky US Army Corps of Engineers (USACE) August 31, 2006

The Solution - SEDD

- SEDD Staged Electronic Data Deliverable
- Staged Approach Allows for Meeting Diverse Reporting Requirements
- Eases Data Exchange between Various Parties
- Analytical Data Delivered in eXtensible Markup Language (XML) Format (Non-Proprietary)
- XML Is Designed for the Creation of Complex Documents and for Input into Various Databases

August 31, 2006

A Technical Overview of SEDD/ Joseph F. Solsky

XML – A Self-Defining Data Format

- Final Recommended Standard by the World Wide Web Consortium
- Each Piece of Data in XML Has a Tag (or Is Tagged) so the Data Set (EDD) is Self-Defined
- Under SEDD, the EDD from the Laboratory Is Transmitted as an XML Document Based on a DTD or Schema

August 31, 2006

Example XML File

<ReportedResult>

- <AnalyteName>Benzene</AnalyteName>
- <CASRegistryNumber>71-43-
- 2</CASRegistryNumber>
- <Result>24.2</Result>
- <ResultUnits>ug/L</ResultUnits>
- </ReportedResult>

A Technical Overview of SEDD/ Joseph F. Solsky

What Is SEDD?

 Uses a common syntax to describe diverse laboratory activities and report analytical data electronically.

- Allows users to link analytical data to underlying laboratory activities and processes to provide full traceability.
- Provides a means for reporting complex analytical relationships.

August 31, 2006

The Stages of SEDD

- Stage 1 Contains the minimum number of analytical data elements required to transmit results-only data.
- Stage 2 Data content builds on Stage 1 by adding method (Stage 2a) and instrument (Stage 2b) Quality Control (QC) data.
- Stage 3 Data content builds on Stage 2 by adding additional measurement data to allow for independent recalculation of the reported results [e.g., Contract Laboratory Program (CLP)].

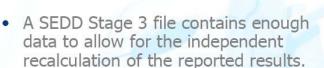

August 31, 2006

A Technical Overview of SEDD/ Joseph F. Solsky

Stage 3 SEDD Files

- Raw instrument data would generally not be used. Corrected instrument data, such as peak areas or corrected intensity readings, would normally be captured.
- This file contains all of the linkages to relate all calibration data and other data to each reported result.
- This file contains information to associate all standards used to their original vendors and lot numbers.

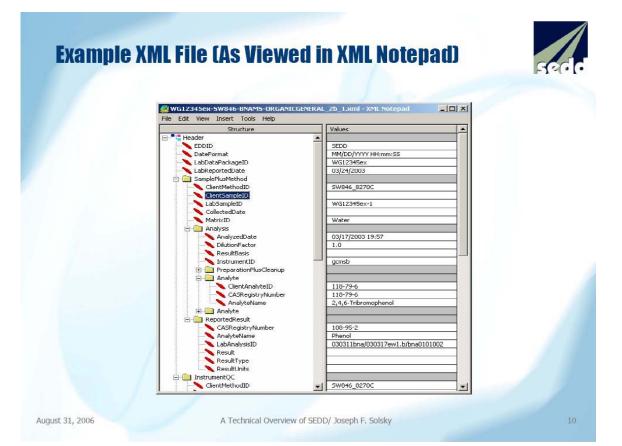

The Future – SEDD Stage 4

- A Stage 4 file uses the same structure as Stage 3 but includes all instrument raw data files that were generated during the analysis of the sample. Other supporting files could also be included.
- These instrument raw data files are stored in a nonproprietary XML format.
- Significant advantages can be realized when data is delivered at this level.

August 31, 2006

What Are Document Type Definitions (DTDs)?

- Would specify what parts of the SEDD structure (nodes) are required.
- Would specify what data elements are required for each node.
- Three stages have now been defined. Data can be delivered based on the amount and complexity of the data required by the user. Generic DTDs are developed for Stage 2a, 2b and 3.
- Schemas can also be used in place of DTDs.

August 31, 2006

A Technical Overview of SEDD/ Joseph F. Solsky

...

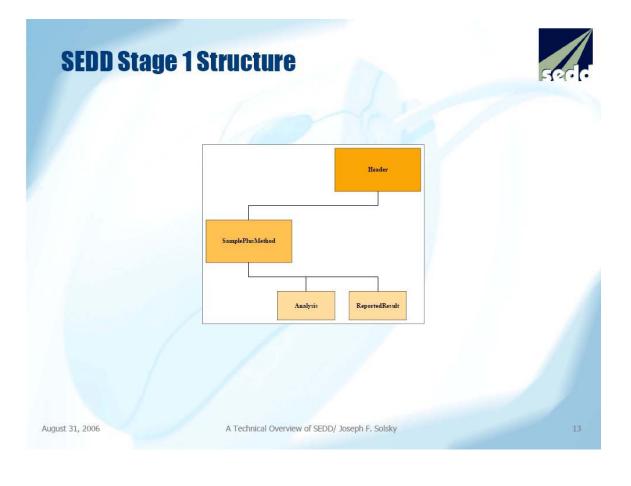

The Valid Value Issue

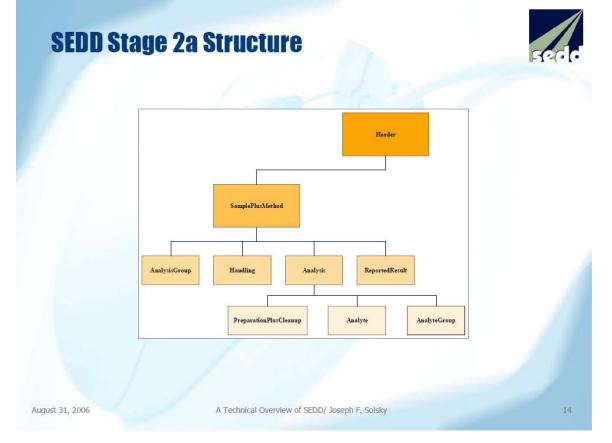

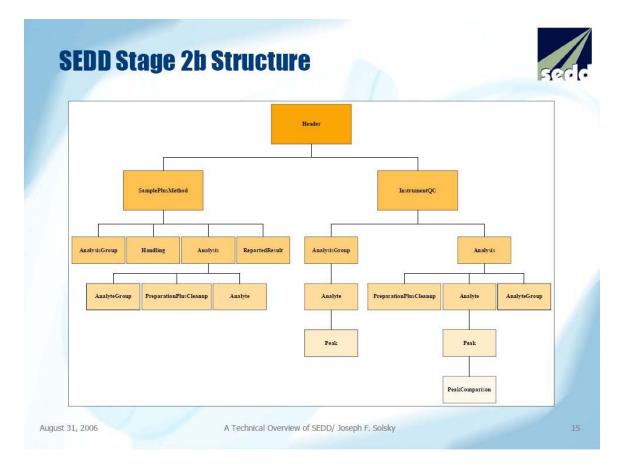

- SEDD now includes a set of valid values.
- Whenever possible, all valid values were tied to an existing standard or recognized database of values. When valid values are reported, they are reported with the appropriate source identified.
- All critical data, such as analyte and method IDs, can be identified using laboratory, client, and referenced values.

AnIML FOR INTERCHANGING ANALYTICAL DATA

Kramer, Gary W.; National Institute of Standards and Technology

Interchanging analytical data and their associated "scientific metadata" across space and time, from instrument to application, application to application, and applications to/from databases has often been hampered by multiple, incompatible data formats. The rapid pace of information technology and computing hardware innovation has exacerbated this problem. Analytical information stored on early digital media (let's say 8-inch floppy disks) 20 years ago may be less accessible today than such information stored on paper 20 years before.

ASTM SubCommittee E13.15 on Analytical Data is creating AnIML to describe chromatography and spectroscopy data and metadata. Based on XML (eXtensible Markup Language) and its associated technologies, AnIML facilitates access to analytical data by building in descriptions of the data and metadata with delimited tags in the same way that HTML (HyperText Markup Language) describes the display of items on a webpage. AnIML is built around a core schema that defines ways for describing almost any data. Technique Definition files are created to constrain the data description mechanisms for a given analytical technique to those commonly accepted for a given technique, to delineate the metadata items commonly associated with such domain data, and to permit content extension by vendors and users without changing the core schema. Once in AnIML format, analytical data can be interchanged over the web, converted to other formats, validated, or visualized in multiple formats using existing XML-based tools. AnIML ensures the integrity of the data through the use of digital signatures and provides for the data tracking, verification, and validation necessary for use in regulated industries.

Analytical Information Markup Language

A New Mechanism for Interchanging and Archiving Analytical Chemistry Data

Gary W. Kramer

Biochemical Science Division National Institute of Standards and Technology

In the beginning...

- Consortium on Automated Analytical Laboratory Systems (CAALS)
 - CAALS-I Communication Protocol
 - High-Level Communications Protocol
 - Common Command Set
 - Device Capability Dataset
- Laboratory Equipment Control Interface Specification (LECIS) - ASTM E1989-1998.
- System Capability Dataset
- How to Deal with Result Data?
- NIST In-House Data Interchange/Archiving Needs

NIST

NIST

Why should I care? Scenario 1

- I just want to paste a chromatogram from our data system into a Word document. But the @#\$%& thing seems to be stored in some kind of in binary format.
- I just want to copy a peak table into a spreadsheet. What happened? It looks like the transporter beam scrambled my data.

I'd like to be able to look at, expand, plot,... that xyzoscopy data that my colleague at EJU sent me. What do you mean I have to buy the vendor's \$5K softwar package? I just want to look at the @#\$%& data.

NIST

Why should I care? Scenario 2

- We did that study before. The data are all here... on these DEC 8 inch floppy disks...
- If I could just open & read this file, I wouldn't have to.... But it's a Visicalc file that requires the CP/M operating system.
- This old NMR data "might" be valuable, but the tapes on this shelf take up too much room.
 I'll bet all their contents would fit onto a a couple of DVDs.
 Know anybody that has a 9-track tape reader interfaced to a PC?

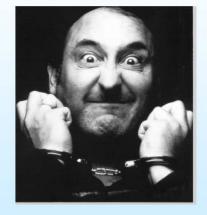

Problems with Current Result Data Handling Mechanisms

- Native Data Formats
 - Proprietary Formats
 - "Metadata" Separated from Result Data
 - Metadata & Data in Multiple Files
 - Metadata Not Available in Electronically
 - No Way to Link Metadata with Result Data

Interchange Data Formats

- Available for Only a Few Important Techniques
 - ♦ ANDI GC, LC, MS
 - ◆ JCAMP-DX IR/FTIR, NMR, UV/Vis, IMS
- Fixed Order, Fixed Syntax, Immutable Formats
- Content Limitations
- Inconsistent Implementations

Formats Incompatible with Modern Network Technologies

Goals for New Result Data Handing

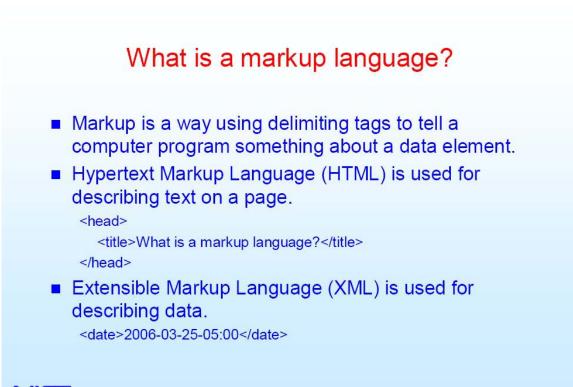

- Extensible
 - Easy to Add New Elements without Breaking Existing Applications
- Flexible
 - Useful for Diverse Needs: Interchange, Interconversion, Archiving...

Useable & Maintainable

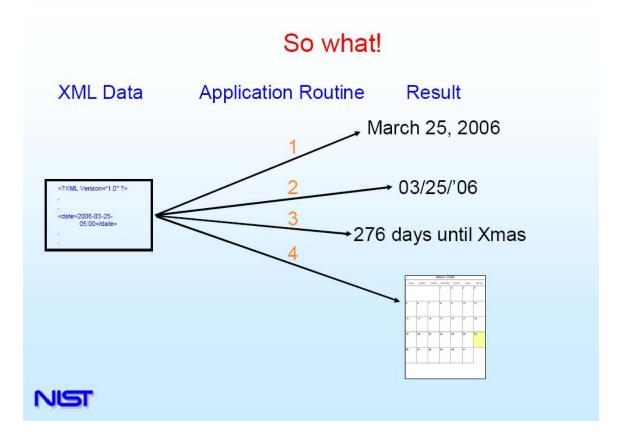

- Easy to Create, Use, Adapt, Maintain ...
- Readily Available Tools
- Acceptable
 - Use Standard Mechanisms Accepted by Mainstream Computing
- Network Friendly

Extensible Markup Language

NIST

XML in 10 Points

- XML is for structuring data
- XML looks like HTML
- XML is text, but is <u>not</u> meant to be read
- XML is designed to be verbose
- XML is a family of technologies
- XML is new, but it has a history & a heritage
- XML turns HTML into XHTML
- XML is modular
- XML is license-free, platform-independent, and wellsupported
- XML is a standard maintained by the W3C

NIST

SpectroML

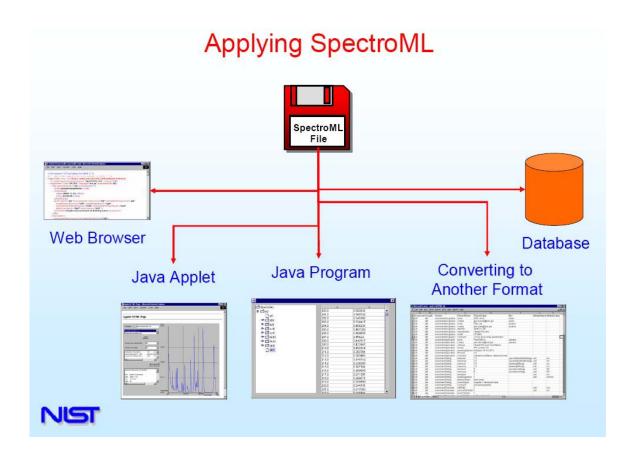

- SpectroML is a markup language for spectroscopy data based upon:
 - XML

NIST

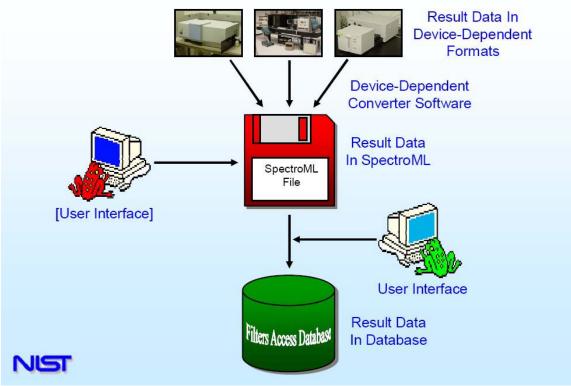

- JCAMP-DX (IUPAC)
- ANDI/NetCDF (ASTM)
- Thermo-Galactic GRAMS and SPC file format
- Data definitions from instrument manufacturers
- ASTM Definitions
- SpectroML is defined for UV-Visible spectral data

vw.w3.org/XML/1999/XML-in-10-points

Applying SpectroML at NIST

Generalized Analytical Markup Language (GAML)

- Represent Analytical Data from Multiple Spectroscopy & Chromatography Techniques
- Compact, Simple Dictionary & Hierarchy (Schema)
- Use XML Datatypes & Hierarchical Structure to Mimic Relationships in Data Sources
- Avoid Parameter "Mapping" Problem
- Minimize the Need for Complex Dictionaries
- Permit Future Expansion
- Keep File Sizes Small

NIST

James Duckworth, Thermo LabSystems

An XML-Based Standard for Molecular Spectrometry and Chromatography Result Data

- Possibility of XML-Based Approach Raised
 - ASTM E01.25 and E13.02 Meetings PittCon '00 Atlanta
- Demo of SpectroML and Applications
 - ASTM E13.01 Meeting PittCon '01 New Orleans
- First Organizational Meeting Held

- Task Group Organizational Meeting
 - ASTM E13.01.03 Meeting PittCon '02 New Orleans
- Task Group Working Meeting
 - ASTM E13.01.03 Meeting Shimadzu, Inc. 9/'02
- New Subcommittee Meeting
 - ASTM E13.15 Meeting PittCon 3/'03 Orlando
- E13.15 Meets at EAS and PittCon

AnIML an XML-Based Standard for Analytical Result Data

- SpectroML and GAML serve as starting points for an XML-based standard interchange format for molecular spectrometry and chromatography.
- Instrument manufacturers, data system & LIMS developers, software developers, end-users, consensus standards organizations, regulatory agencies, and other interested parties are invited to participate in this effort.

Creating Analytical Information Markup Language (AnIML)

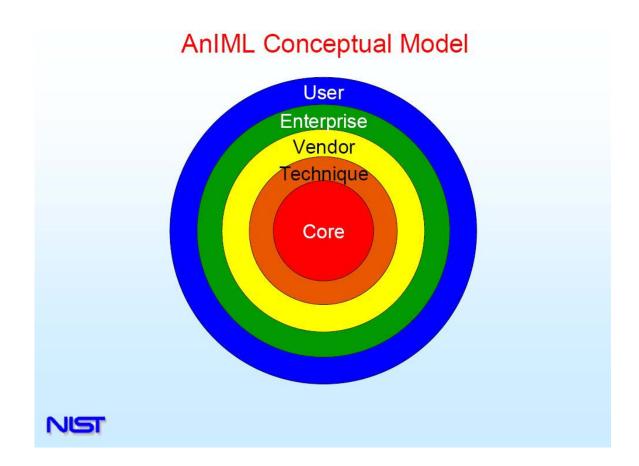

- Creating AnIML does <u>NOT</u> mean "starting over."
- AnIML should be built on existing ASTM, IUPAC, instrument vendor, and LIMS-developer efforts to define common data dictionaries.
- Once the schemas for AnIML are in place, straightforward translators can be written to bridge current datasets to the new standard.
- AnIML should be developed in a way that makes it extensible to multiple techniques, yet avoids duplication of effort and dictionary entries.

Key Features of AnIML

- Extensible
- Can Accommodate ANY Type of Data
- Validateable
- Traceable through Audit Trails
- Verifiable Using Digital Signatures

NIST

AnIML Components

- AnIML Core Schema
 - One Schema
 - Maintained by ASTM E13.15
- AnIML Technique Schema
 - One Schema
 - Maintained by ASTM E13.15

AnIML Base Technique Documents

- One Instance Document per Technique
- Maintained by ASTM E13 or Appropriate Domain Expert Organization
- AnIML Extended Technique Documents
 - One Instance Document per Technique Created from the Appropriate Base Technique Document
 - Maintained by Vendor, Organization, User, or Whoever Extends the Technique
- AnIML Result Data Files

NIST

Considerations for Terms & Concepts in the Core

- Is the term/concept shared by most spectroscopy and chromatography techniques?
- Is the term/concept used in most datasets collected by most spectroscopy and chromatography techniques?
- Items that software needs to "understand" must be fundamental elements.
- Items that software only need for display and/or reporting can be more generically represented.
- Representations must be consistent with the requirements of FDA's US 21CFR11 and ISO 17025.

AnIML Naming & Design Rules

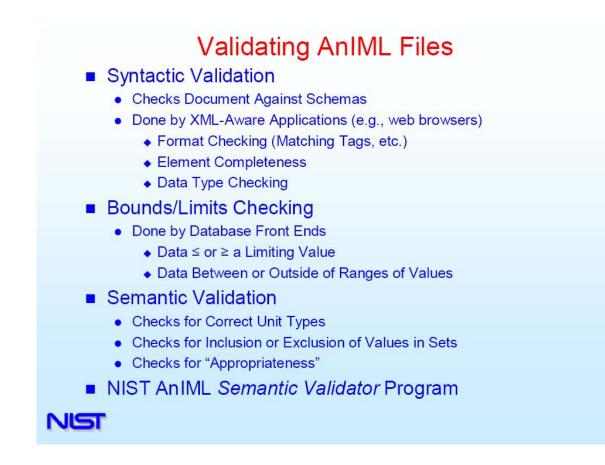

- Rules for organizing content
- Rules for generating element names
- Rules permit reuse, minimize duplication
- Rules limit ambiguities of human language
- Rules simplify design of applications
- Rules enhance interoperability
- Rules versus "Guidance"
- Encoding rules to permit automatic validation

NIST

UnitsML

- Most markup languages need to deal with quantities & units
- Why not create a definitive markup language & schema to encode units into XML that can be used with all other markup languages?
- UnitsML allows the unambiguous storage, interchange, & processing of numeric data
- Using UnitsML
 - Incorporation
 - Import
 - Include
 - Referencing
- OASIS Units Markup Language (UnitsML) Technical Committee (coming soon)

NIST

Creating, Modifying, and Extending AnIML Technique Documents

- Requirements:
 - Domain Expertise
 - XML Expertise
- Problem: The requirements seem to be nearly mutually exclusive.
- Solution: The WICIL/NIST Technique Creator Program
 - Utilizes the AnIML Core Schema, AnIML Technique Schema, and AnIML Base Technique Documents
 - Provides Graphic Visualization of Technique Document Structure
 - Provides Step-by-Step Editing Guidance
 - Creates the XML Code

E13.15 Deliverables (Software)

- AnIML Core Schema
- AnIML Technique Schema
- AnIML Technique Definition Documents for:
 - UV/Vis
 - IR
 - NMR
 - Mass Spec
 - Chromatography
 - IMS
- AnIML File Validator
- Generic AnIML Viewer
- AnIML Example Files

NIST

E13.15 Deliverables (Documentation)

- AnIML Core Standard
- AnIML Core User Guide
- AnIML Technique Standard
- AnIML Technique User Guide
- Naming and Design Rules for the AnIML Core
- Naming and Design Rules for AnIML Techniques
- AnIML Technique Definition Documents for:
 - UV/Vis 🏨
 - IR 🚇
 - NMR 🕮
 - Mass Spec
 - Chromatography
 - IMS

NIST

FAQs

- What if we don't get it right the first time?
- What happens when more "definitive" schemas appear?
- We/I don't like the definitions in the lower levels.
- What if new extensions of the technique emerge, new techniques are invented, or techniques are "hyphenated?"
- Can XML handle my variable temperature, pH-gradient, LC-MS-MS/PDA/NMR data?
- Since XML is text, how can data tampering be avoided?
- What do we do with our bazillions of JCAMP (or ANDI or...) spectra?
- Is XML the ultimate solution?

Long Term Storage of Chromatographic Data

Dale O'Neill

Agilent Technologies, 6612 Owens Dr., Pleasanton, CA 94588

INTRODUCTION

Imagine you are in a court room and are facing litigation. The court rules for the opposing party, saying that you are to produce records for the last 20 years of data. In the past, companies that have found themselves in this predicament have spent millions of dollars extracting information from old tapes. Others extracted information only to have their findings rejected because they did not understand the difference between an electronic file and electronic data. If a court demands records and you spend hours retrieving, printing, and reviewing documents, and then turn this over to a court, a savvy lawyer might ask, "What about the hidden data?" He might add, either this company is incompetent or they are hiding something. Your company might complain that to go back and retrieve the data again is costly and burdensome, but the courts will insist it is your data, you organized it that way, and therefore it is your responsibility to collect it and turn it over to the court.

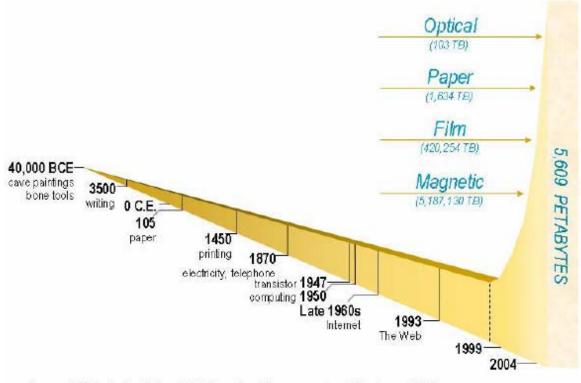

Since over 50% of data is not printed, lawyers on both sides must be able to look into the computer, and you are responsible for retrieving that data and giving it to the courts or regulators. If you have not taken care to properly preserve the data, you will be forced to hire Information Technology specialist, software developers, and data reviewers to extract this information for you. This could be an economic hardship on the company.

Whether it is litigation, or to validate HIPAA, Sarbanes-Oxley, or FDA's 21 CFR Part 11 compliance, the need for data preservation is important. Even if you are not concerned at this time about data preservation and litigation, your customers are, and they will in the future come and ask you to be part of a solution.

Data Preservation is important. It covers Electronic Discovery, Record management, Application and Data Life Cycle, Maintenance, and Migratory patterns. My focus is on Application and Data Life Cycle and how this contributes to the solution of data preservation.

MORE DATA

According to a report by UC Berkley's School of Information Management and Systems, over the next several years more data will be created than in the previous 300 years combined.

Source: UC Berkeley, School of Information Management and Systems, 2003

Figure 1

DIFFERENT SOURCES AND DATA TYPES

This data is in various proprietary formats of which some is well structured and others not structured. Some data is stored on disks and others in databases.

RETENTION PERIODS

Because of this mass amount of data and the many proprietary formats, regulations are now surfacing requiring companies to make their data retrievable for the next 10 to 30 years. Some SOP's require the data to be accessible for up to the next 100 years.

This has created many headaches in the industry. With many vendors continuing to create new applications and new data formats while at the same time not given adequate support for old applications and old data formats, the problem will only continue to grow.

APPLICATION LIFE CYCLES

When a new need arises, applications are created and released. Shortly after release bug fixes are made and service packs distributed. Next, enhancements are made in minor revisions. And then the application peaks and a new OS is in sight. New and wonderful technology is promoted, a new compiler is made, and shortly therein the old application has started to be forgotten.

But what happens to all this data that has just been created from this old application? Do we archive or delete it? Where is the old application and is it still being supported by the creating

company? Will the new application be able to import the old data? Can another application import this data? How easy or difficult is it to import this data? Where is our retention policy manual and can anyone understand it?

THE NEED FOR TECHNOLOGY NEUTRAL FORMAT (TNF)

Critical data must be preserved in its entirety. Partial data like electronic paper is not good enough. The data must be "brought forward" and useable for viewing and analysis. This means it must be OS independent and outlive the original application. It must be human readable, that is, not in binary or proprietary format.

THE PROBLEMS WITH MULTIPLE TNF FORMATS

There are current applications meeting some of these requirements. They create a standard that is OS independent, and can be human readable, and can even be imported into the next version of the software. And of course it is the best format because "we did it and we know best, as our sales people have already pointed this out to you".

Unfortunately, this happens all too often in the technology world and the side affects are costly. These proprietary formats have little or no interoperability. Multiple viewers and analysis tools must be created and supported. Proliferation of yet another format is created and sometime in the future this data will have to be imported/exported along with the other proprietary formats.

THE ADVANTAGES OF A STANDARDIZED FORMAT

On the other hand, when using a standard format, the exchange of data is made tremendously easier. You don't have to send a request to engineering to write a converter. There is a consistent and well-known architecture. All the vendors you could say talk the same language. Tools can be used and designed to work across versions. Generic tool sets can now be made available and used. This would be equivalent to email. There are many email applications available, but the standard for sharing email is well defined. How these applications work are proprietary, but the data is well described so all can view, reply, and exchange information. If vendor X stops making his email application, there are many other applications that will continue to support and maintain your email capability.

AnIML TO THE RESCUE

To help solve these problems Analytical Information Markup Language called AnIML has been developed. AnIML is an XML standard for analytical chemistry data. It is the collaborative effort between many groups and individuals and is sanctioned by the ASTM.

AnIML is a standard format that is a structured text file using xml technologies. AnIML is generic and not vendor specific. You can view AnIML with any text editor, like Notepad. AnIML is all-inclusive. Every bit of data from an entire experiment can be represented and stored in an AnIML file.

MAPPING DATA INTO AnIML

To begin using AnIML you need to start mapping your data. To do this you need to start educating yourself on the following two topics, AnIML Core Schema and AnIML Technique Documents.

AnIML Core Schema

The AnIML core schema is the heart of AnIML, and ultimately defines all structure and data types found in an AnIML file.

AnIML Technique Documents

AnIML technique documents are schemas that define a particular analytical technique. A technique is similar to describing a type of automobile such as a truck, bus, or passenger vehicle. All these vehicles work off a core premise of an engine, wheels, seats, mirrors, etc. But where you place these items in the different vehicles is the "technique". A technique specifies the type of AnIML document you are creating.

For example, if you were to map Peak Position and Peak Height into AnIML, several locations would be acceptable to the AnIML schema. The figure below shows the data being placed in either a Vector or Parameter Category Set. So the question begs, "Which one is correct," or "Where should I place my Chromatography data?"

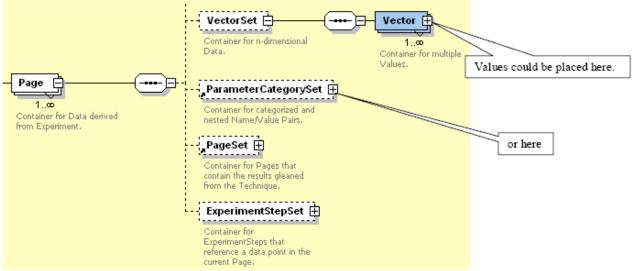

Figure 2: Location of Values without Technique

The answer is found in the Technique document. The Technique document for Chromatography data tells us to place these items inside a Vector and to call them PeakPosition and PeakHeight.

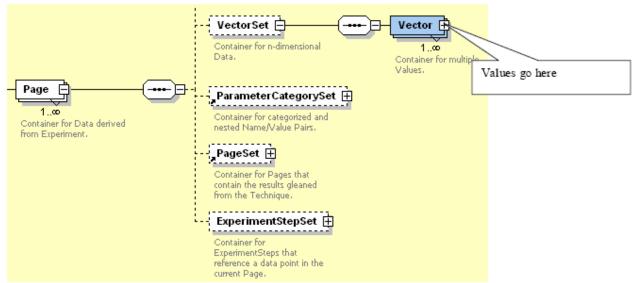

Figure 3: Location of Values Based on Technique

CUSTOMIZABLE ARCHITECTURE

Technique documents cover common values such as PeakNumber, PeakPosition, PeakArea, etc. So what do you do with custom data system values such as Area to Height ratio or Peak Integration Events?

The core schema of AnIML provides for storage of custom data through a concept called ParameterCategorySets. The data stored here is still structured and can be viewed by generic viewers. Below is a generic viewer displaying Custom Results. Although the viewer does not understand custom data, it does understand how to display an AnIML CustomParameterCategorySet.

Figure 4: TNF Viewer

LARGE AnIML FILES

It should also be noted that a typical Chromatograph AnIML file can easily contain 50,000 plus lines of text. These lines include such information as:

- General File Information
- Method Configuration
- Instrument Configuration
- Injector Configuration
- Calibration Information
- Raw Data Results
- Peak Results
- Revision Information
- Other Data

Developers need to be aware of the size requirements, and design tools/viewers for speed from the ground up.

BEST PROGRAMMING PRACTICES

Encapsulate Logic to Write Sections of the AnIML File into Object Classes AnIML core is made up of defined structures/objects such as ParamaterCategorySets, PageSets, Pages, Templates, etc. Creating these known objects encourages code reuse and makes enhancements easy.

Maintain a Level of Indirection between Source Data and the AnIML File

When maintaining a level of indirection between source data and the AnIML file you put yourself in a position to handle future changes. If a new feature and/or version of the AnIML schema is released, changes are easily accommodated.

Tools, Applications, and Viewers Should Operate on the Indirect Data

Tools, Applications, and Viewers, created should operate on the indirect data. When changes occur upstream, these applications will continue to work unmodified, once the intermediate object classes are changed.

SUMMARY

It is important that we do not leave key data in irreconcilable formats. Saving or storing data might seem like a simple act. But how will today's data appear to those in the future. We need to 'future-proof' today's digital data so that it can be regenerated in the computer applications of tomorrow.

Analytical Instrument Markup Language (AnIML)

Long Term Storage of Chromatographic Data...

AnIML, TNF, Viewers, and Plenty of Challenges!

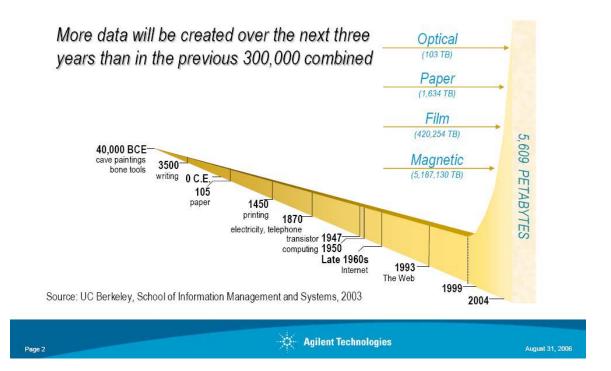

Dale O'Neill Agilent Technologies

🔅 Agilent Technologies

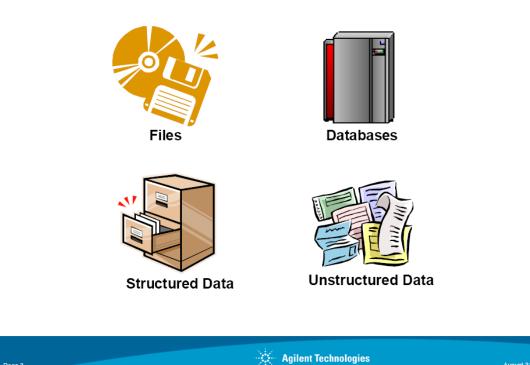

August 31, 2006

More and more data...

Page 1

Different sources and types of data...

Retention periods...

- Regulations
 - 10, 20, 30 years
- SOPs

Page 3

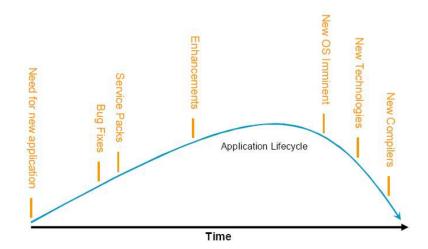

- 40, 50... sometimes upwards of 100 years!

Page 4	Agilent Technologies	August 31, 2006

Application lifecycles

All applications progress through a natural lifecycle.

Page 5 Agilent Technologies August 31, 2006

The need for Technology Neutral File (TNF) formats

Critical data must:

- Be preserved in its entirety
- Be OS independent
- Outlive the creating application
- Must be human readable (not binary or proprietary formats)
- Must be usable today (viewing and analysis)

Structured Text Files

Page 6	Agilent Technologies	August 31, 2006

The problems with multiple TNF formats

- Little or no interoperability
- Must create multiple viewing and analysis tools
- Proliferation of more formats
- Maintenance and versioning nightmare for developers
- New applications must support all previous formats
- "Our format is best" syndrome

Agilent Technologies

August 31, 2006

The advantages of a standardized format

- Easy exchange of data between applications
- Consistent and well known architecture

Page 7

Page 8

- Tools can be designed to work across versions
- Generic tools can be developed and shared
- Shared vendor support for standard format
- Format will be maintained and supported, even if vendors come and go

Agilent Technologies

August 31, 2006

AnIML to the rescue

- AnIML is a standardized file format
- AnIML is a structured text file, using XML technology
- AnIML is generic and is not vendor specific
- AnIML is human readable
- AnIML is all-inclusive. Every bit of data from an entire experiment can be represented and stored in an AnIML file
- AnIML is flexible, while still predictable
- Data in an AnIML file can be tightly constrained for any given analytical technique

Agilent Technologies

August 31, 2006

Mapping data to AnIML

Application developers can begin to map analytical data into AnIML by educating themselves on the following topics:

AnIML Core Schema

Page 9

Page 10

- This schema is the heart of AnIML, and ultimately defines the structure for all data in AnIML XML files
- AnIML Technique Documents

 These schemas define the rules for your structured data, given a particular analytical technique

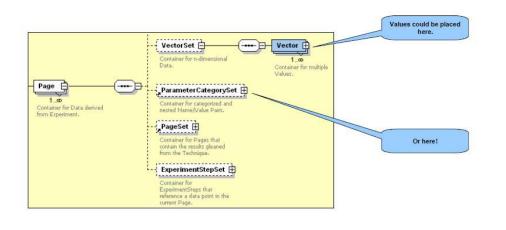

- N. B. M		
	Agilent Techn	ologios
	мунент тесни	luiugiea

August 31, 2006

Mapping data to AnIML

Example

- Mapping Position of Peak and Height of Peak into the AnIML schema
- Without a technique document, where do we put these items, and what are they called?

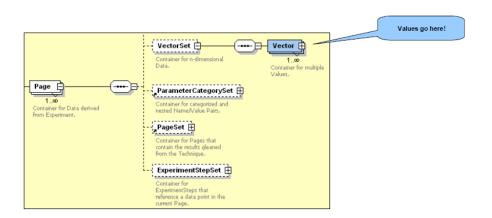

Page 11	Agilent Technologies	August 31, 2006

Mapping data to AnIML

Example

 The technique document tells us to put these items inside of a Vector, and call them <u>PeakPosition</u> and <u>PeakHeight</u>, respectively

Page 12	Agilent Technologies	August 31, 2006

Customizable Architecture

Technique documents cover common values only

Peak Number Peak Position Peak Height Peak Width Peak Area Peak Amount etc.

What to do with custom data system values?

Area to Height Ratio Number of Shoulders Peak Integration Events etc.

Answer...

Page 13

- The core schema provides for storage of custom data through a concept called ParameterCategorySets
- The data is still structured, and can be discovered and viewed by generic viewers

Agilent Technologies

August 31, 2006

Customizable Architecture

--	----------

A typical AnIML file can be quite LARGE

A typical Chromatograph AnIML file can easily be 50,000+ lines of text. Includes items such as:

- General file information
- Method configuration
- Instrument configuration
- Injector configuration
- Calibration information
- Raw data results
- Peak results
- Revision information
- etc.

Page 15

Developers need to be aware of the size requirements, and design tools/viewers for speed from the ground up.

Agilent Technologies

August 31, 2006

Best programming practices

- Encapsulate logic to write sections of the AnIML file into object classes
 - Encourages code reuse, and allows bugs to be fixed in one place
 - Enhancements and changes are easy to make
- Maintain a level of indirection between source data and the AnIML file
 - If new features and/or versions of the AnIML schema are released, changes are easily accommodated

- Tools, applications, viewers should operate on the indirect data
 - When changes occur upstream, the tools will continue to work unmodified, once the intermediate object classes are changed

Demo

- View real AnIML XML file
- View same AnIML file in Agilent's AnIML File Viewer

Agilent Technologies

August 31, 2006

Summary

Page 17

- Massive amounts of data are being generated
- Much of this data must be kept for 30+ years
- Applications retire, but the data must live on, in a TNF format
- AnIML is being created by the ASTM subcommittee E13.15, and is <u>the</u> standard for TNF representations of analytical data
- AnIML is a highly structured, but flexible file format
- Tools, applications, and viewers are already being generated around AnIML

Page 18

Agilent Technologies

August 31, 2006

DEVELOPING AN INTRANET-BASED QUALITY MANAGEMENT SYSTEM TO INCORPORATE MEASUREMENT AND REPORTING

Haddad, Elizabeth – United States Environmental Protection Agency; Worthington, Jeffrey – United States Environmental Protection Agency; Policy and Program Development Staff – U.S. Office of Environmental Information

Quality planning has focused primarily on outputs for many quality management systems resulting in quality documents such as management plans, project plans, assessment reports, and the like. Placing the quality system in an electronic application allows the quality manager and data developer to incorporate the reporting function into the on-site processes. This approach provides for increased manager interaction and encourages the development and use of measurements of the performance of the quality system AND through the quality system, measurements of performance of the enterprise operations. The EPA Office of Environmental Information recently developed their quality system as an intranet web site and is using this approach to manage and report quality for the office. This presentation reviews the advantages of the approach, demonstrates how the OEI quality system is constructed in an electronic environment, and demonstrates how measurements are incorporated into the system.

22nd Annual National Environmental Monitoring Conference

Jeffrey C. Worthington OEI Director of Quality Office of Environmental Information U.S Environmental Protection Agency

Past- Chair, Energy and Environmental Division American Society for Quality

Elizabeth Haddad Quality Program Intern at EPA OEI The Washington Center

National Environmental Monitoring Conference (NEMC) Washington, DC August 27-31

Jeffrey Worthington- BIO

ASQ

- Director of Quality for the USEPA Office of Environmental Information. Jeff served as the Director of Quality USEPA ORD National Risk Management Research Laboratory (NRMRL) and as the Director of Quality Assurance for TechLaw, Inc. He is an American Society for Quality (ASQ) Certified Quality Manager and ASQ Certified Quality Auditor. Jeff, Senior ASQ member, founding member of the Education Division, is the Past-Chair of the ASO Energy and Environment Division and participates on the ASQ Division Affairs Council. He is a founding member and past Director for the recently established International Association for Information and Data Quality (IAIDQ). Jeff served as Editorial Board member for Quality Assurance, Science, and the Law, the Journal of Environmental Forensics, Environmental Laboratory magazine, and Environmental Testing and Analysis magazine.
- He has been with the Federal Government since 1994. Jeff supported environmental engineering quality at NRMRL, joining a team authoring the combined quality and management system for EPA's Environmental Technology Verification program. He co-led the EPA team developing EPA's Information Quality Guidelines. Jeff co-authored a peer review journal paper receiving the USEPA Science and Technological Achievement Award, Level III for equating EPA policies and procedures to U.S. Supreme Court Sound Science Criteria (2002). Jeff has spoken at numerous national and regional conferences on the subjects of quality management, audit management, information quality planning and assessment, data authenticity, data quality, and data integrity.

Elizabeth Haddad - BIO

Elizabeth Haddad is a Quality Program and Regulatory Program intern for The Washington Center. Elizabeth is assigned to the USEPA Office of Environmental Information, Office of Planning, Resources, and Outreach, Policy and Program Development Staff. In her short tenure as an intern, Elizabeth has participated in developing the innovative and interactive web-based OEI quality system, supports quality and information policy development, assists in implementing the OEI quality system, and analyzes Agency policy to facilitate potential integration. Elizabeth is a graduate of Tufts University where she double-majored in International Relations and Middle Eastern Studies.

DISCLAIMER

The opinions expressed in this technical presentation are those of the authors and do not necessarily reflect the views of the US EPA or The Washington Center.

- Describe OEI's newly approved (2/06) Intranet-based Quality Management Plan
- Demonstrate some of its capabilities

What Is OEI's Quality Policy?

OEI will ensure the quality of the OEI products, services, and procedures addressed in this quality system and will meet customer's needs and expectations.

What Are OEI's Quality Principles?

- Principle 1 Information quality includes that part of CONTENT for which we are responsible, as well as DELIVERY.
- Principle 2 We define quality for OEI PRODUCTS and SERVICES to include four basic areas.
- Principle 3 Customer Satisfaction means "Do they respect us? Would they come back to us for products and services?"

What Is a Quality Management Plan (QMP)?

A document that describes an organization's system in terms of its organizational structure, policy and procedures, staff functional responsibilities, lines of authority, and interfaces for those planning, implementing, documenting, and assessing all activities conducted.

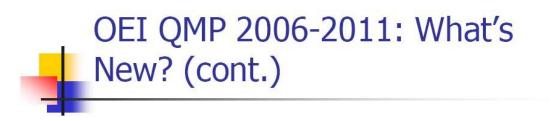

- It's required for EPA organizations by Quality Order 5360.1 A2.
- It's a sound business practice that is expected by OEI's internal and external customers.

Why Does OEI Need a *New* QMP?

- All EPA Quality Requirements Documents are valid for a period of five years, and then must be revised/renewed.
- OEI's previous QMP was due to expire in 2006.

- It's on-line (EPA Intranet)!
- It offers interactive features (e.g., a QAPP template)
- It incorporates reporting features on the same site as the Plan

- It features annual agreements with OEI
 Office Directors on program priorities
- It includes information on new topics (e.g., Information Quality Guidelines compliance)

Major Challenges of an On-Line QMP

- Creating it:
 - Existing EPA guidance and practice assumes a stand-alone document
 - "Go back to basics" to reinvent the essence of a QMP
 - Create an integrated (nested) system rather than a collection of pdf files

Major Challenges of an On-Line QMP (cont.)

- Reviewing/approving it:
 - Following links
 - Tracking processes
 - Ensuring completeness
- The EPA Quality Staff did an admirable and thorough job

- Description
- Tools
- Reports
- Records
- Resources
- Training
- Processes

Pending Quality Policy Changes

- Like every other Agency QMP, this will change due to upcoming broadening of the Agency's quality policy
- We have a head start this QMP points in the direction the Agency is heading

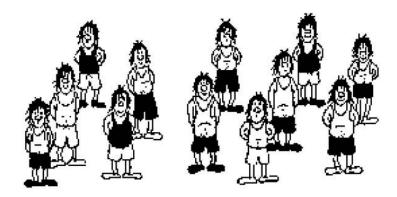

Contact: Jeff Worthington 202-566-0995 Worthington.Jeffrey@epa.gov

No. of Concession, Name

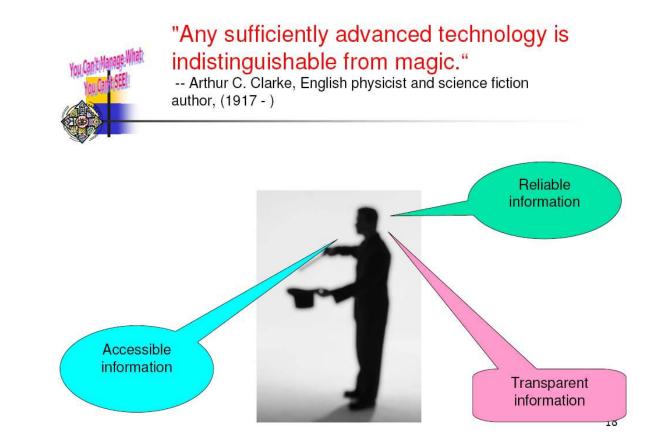

OVERVIEW You can't manage what you can't see.

- I. Introduction: What is needed to move toward a consensus measurement model
- II. Basic concepts of information quality
- III. Basic concepts of environmental measurement models
- IV. EPA needs and perspectives
- $V_{\text{-}}$ The impact of current EPA quality and information policies and standards
- VI. A model for EPA
- VII. Next steps

You Can't Manage What You Can't SEE!

- •Eye of Providence "builders of the past"
- •All-Seeing Eye (of Deity) Masonic reference
- Obverse of Great Seal of the U.S.
 Novus Ordo Seclorum A new order of the ages
- DaVinci Code movie
- •National Treasure movie

Obverse of The United States Great Seal

The basic tool for the manipulation of reality is the manipulation of words. If you can control the meaning of words, you can control the people who must use the words.

- Philip K. Dick, American writer, *I Hope I Shall Arrive Soon*, 1986 You Can't Manage What You Can't SEE!

The basic tool for the manipulation of data is.....

The basic tool for the manipulation of data is the manipulation of the words that describe the data.....

To give environmental measurements value:

The basic tools for capturing, recording, manipulating, using, disseminating, and archiving information are:

•Standard procedures and process to develop information content

•Standard procedures and processes to ensure consistent information format, and

• Standard procedures and processes to ensure consistent information functionality.

If you can control all these processes, you can control and ensure effective use of the information – including environmental measurements.

Why would a national consensus model improve environmental measurements?

Standard content, format, and function of information in environmental measurements leads to improved:

- Consistency
- Completeness
- comparability

What changes might take place?

- Need to accommodate consensus approach during planning
- Recognition that data and information (environmental measurements) have a lifecycle

If you don't control the information aspect of your environmental measurements – format, content, and functionality –

Floccinaucinihilipilification of the environmental measurements will occur

Floccinaucinihilipilification

"estimating something as worthless"

Floccinaucinihilipilification

FLOK-si-NO-si-NY-HIL-i-PIL-i-fi-KY-shuhn

Flocci+nocci+nihili+pili+fication

What is needed to move towards a national consensus model for environmental information measurement?

An understanding of what has changed

EPA before

- Env. Data to support decisions
- A receiver of data
- A provide of data reports
- Flexibility in formats for improved quality

EPA now

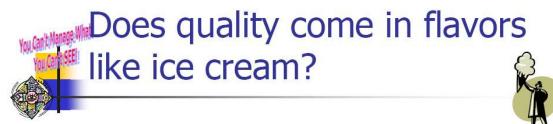

- An information resource
- A conduit to data owned by others
- A provide of tools to selfselect your own reports
- Flexibility for you access, but not in formats

- Standard language
- Recognition of key components
- Agreement on what is important
- Agreement on why it is important and what is its value
- Identification and involvement of stakeholders
- Recognition of challenges and approach to resolve
- Systematic approach to implement AND maintain

- Relevant policies
- Procedures
- Data and other standards
- Guidelines
- (increased interoperability between users)

- Environmental measurements are a type of information
- Information quality is more than just the environmental measures
- EPA is already actively dealing with the concept of information quality

EPA already has drivers for information quality in the Federal Government

- General accountability to the public
- Support the enterprise mission
- Meet required enterprise program statutory specifications
- Federal information quality requirements
- Clinger-Cohen Act (Chief Information Officer Responsibilities)
- President's (electronic government) E-Government Strategy, E-government Act of 2002
- OMB information policies
- Enterprise's information policies

EXAMPLE Office of Management and Budget and Information

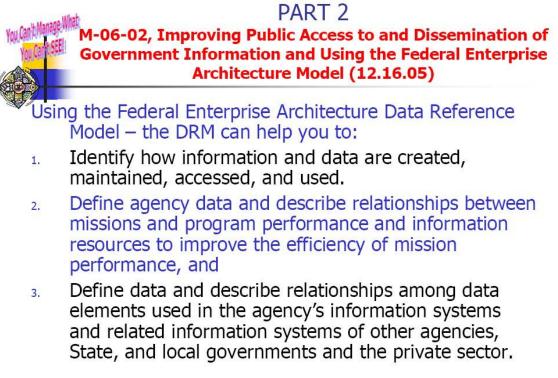

- Office of Management and Budget

 - Privacy guidance
 - Privacy reference materials
 - Government Paperwork Elimination Act (GPEA)
 - Freedom of Information Reform Act

33

Marchitecture Model (12.16.05)

3 new requirements

- Organize and categorize your information for public access, make it searchable across agencies, and describe how you use formal information models to assist your dissemination activities
- Review the performance and results of your information dissemination program and describe the review in your Information Resources Management (IRM) Strategic Plan
- Publish you IRM Strategic Plan on your public website (if not doing this now, do this by 09.01.06)

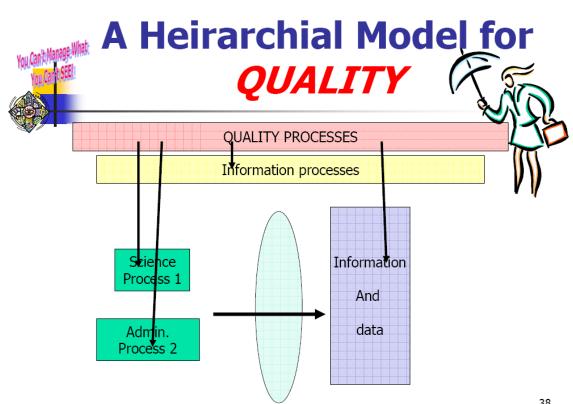

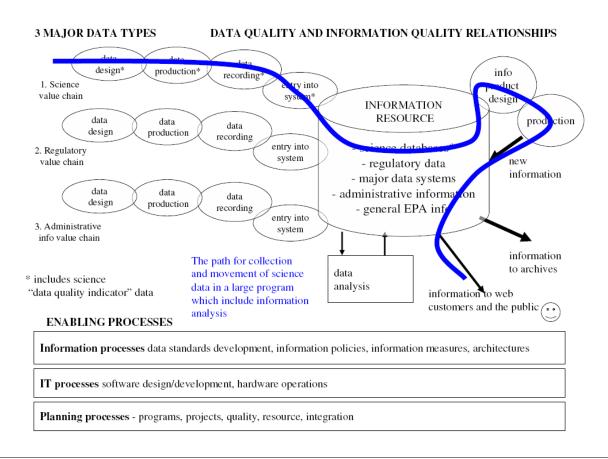

Basic concepts of information quality

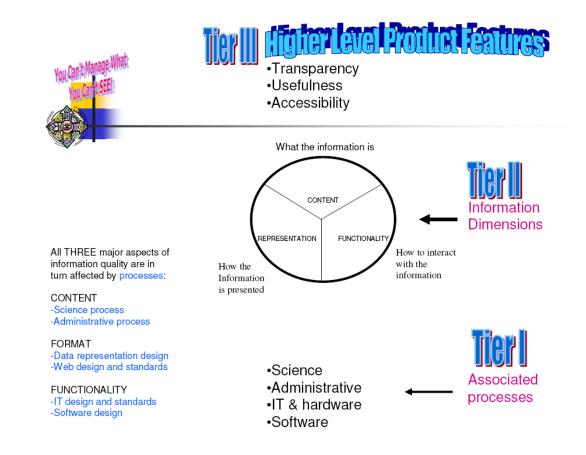

Ensure the quality of:

- the real processes (science and technology) before production of information AND
- The quality of the resulting information

EPA needs and perspectives

Traditionally focused on:

- Decisions about the environment
- Measurements of the environment to support those decisions

Areas that also must be addressed:

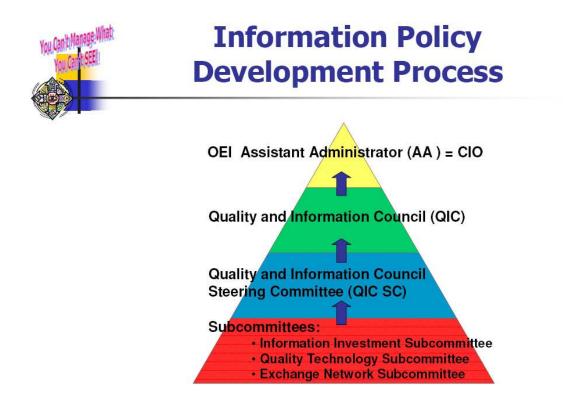

- EPA serves as a owner of historical information in large data sets
- EPA serves as a pathway to access information and data of others
- EPA serves as a provider on information services that allow citizens to access information and data through "information products" or "information tools."
- EPA must understand data and information needs from the stakeholders perspective

43

Example Quality Policy

- 1. Information quality includes that part of CONTENT for which we are responsible, as well as DELIVERY.
- 2. We define quality for OEI PRODUCTS and SERVICES to include 4 basic areas:
 - Functions: Does it have the functions and features I want?
 - Internal Controls: Does it work? Do we have adequate internal controls to avoid errors or defects? Do defects prevent me from using it?
 - Customer service: Do customers get the service that they expect, and is it on time?
 - Efficiency: Did I effectively use my resources in the process? Are we on time and on budget?
- 3. Customer Satisfaction means "Do they respect us? Would they come back to us for products and services?"

What is EPA's model now for planning and controlling the quality of Agency information?

Information Resources Management (IRM) Policy Manual

Data Standard Example 1

Chemical Identification data standard: consists of a series of "data elements"

NAME	DEFINITION	N TYPE		
Chemical Abstracts Service Registry Number	The unique number assigned by Chemical Abstracts Service (CAS) to a chemical substance	Alphanumeric (9) Mandatory	Standard /final	
Chemical Substance Systematic Name	A standard name assigned to a chemical substance	Alphanumeric (2000) Mandatory	Standard /final	
EPA Chemical Identifier	The identifier to be created and placed in the SRS for each chemical substance or chemical group in the SRS for which a SAS Registry Number does not exist and cannot be assigned	Alphanumberic (9) Mandatory	Standard /fina Standard /fina	
EPA Chemical Internal Tracking Number	The unique record number assigned to a chemical substance or a chemical grouping for tracking within EPA systems	Alphanumberic (9) Mandatory		
EPA Chemical Registry Name	The name US EPA has selected as the preferred name for a chemical substance	Alphanumberic (9) Mandatory	Standard /final	
Chemical Preferred Acronym Name 14 additional data elen	The name US EPA has selected as the preferred acronym or otherwise abbreviated name in the SRS for a chemical substance, when use of a shortened name in	Alphanumeric (2000) Mandatory	Standard /final	

Information Content: Code Sets

CODE SETS contain permissible values, value meaning names, and value meaning definitions that can be used in applications. They can be associated with EPA data standards, national/international standards, or contain lists of values commonly used by EPA programs.

Code sets help ensure consistency of content quality.

57

Code Set Examples

Examples:

- Country names
- County names
- State names
- State codes
- Geometric type codes
- Verification method codes
- Vertical collection method codes
- Vertical collection method names

Information Content:

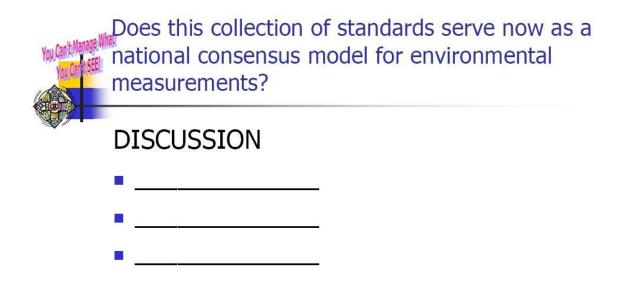

XML and XML Tags Standard Tags

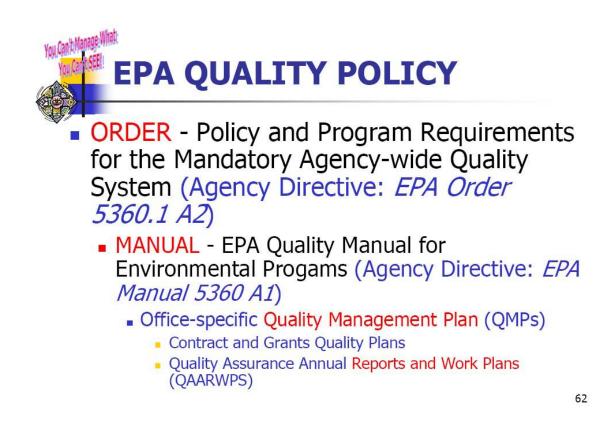

- XML tag = the name for a "data element" used for XML programming in web applications
- XML tags are for each data element in a data standard and for other accepted uses

EPA: EPA Data Standard : - Microsoft Internet Explorer

Re-defining *QUALITY*

Quality addresses all products and services in the following areas: $\ensuremath{\mathsf{PROCESSES}}$

- Environmental and related science applications
- Engineering applications associated with environmental applications
- Administrative operations that result in information and data that are considered to be a resource of the
 organization
- INFORMATION TECHNOLOGY
- Hardware reliability and maintainability
- Software design controls
- Configuration and operational conformity
- INFORMATION MANAGEMENT
- Database quality
- Information modeling functionality
- Data standards and associated standards conformity
- INFORMATION OPERATIONS
- Web operations
- Web standards conformity
- GENERAL INFORMATION QUALITY CONSIDERATIONS
- Information guality include both information content and information delivery
- Information quality covers the following 4 areas
 - Information features
 - (reasonable) freedom of defect
 - Customer service
 - Cost efficiency
- Customer satisfaction

National Consensus Model ENVIRONMENTAL MEASUREMENTS

INTER-RELATED STANDARDS TO ACCOMMODATE CONTENT, FORMAT, AND FUNCTIONALITY ASPECTS OF ENVIRONMENTAL MEASUREMENTS INCLUDING:

CONTENT - for each environmental measurement type

- Library of data standards for environmental measurements (e.g., measurement values, PARCCS)
- Geospatial data standards (done!!)
- Library of data standards for "associated data" (e.g., location, well information, site conditions, etc.)
- Library of data standards for "metadata" (e.g., data descriptors contained in data standards)
- Data Provenance standards to describe possible "levels" or methodology to offer some form of data provenance

FORMAT - (PRESENTATION)

- Information standards for presentation formats (e.g., tabular, map)
- Web presentation standards (e.g., transparency objectivity options)
-for its intended purpose
- Standard description methods
- Geospatial formatting

INFORMATION FUNCTIONALITY

- Standard for terminology for naming and interacting with environmental measures
- Standard modeling interactions

DATA BASES AND DATA MANAGEMENT

- Standard methodology for database management functions
- Standard methodology for records management for large data collections

National Consensus Model ENVIRONMENTAL MEASUREMENTS

WILL LEAD TO IMPROVED UNDERSTANDING AND IMPROVED QUALITY OF ENVIRONMENTAL MEASUREMENTS WHICH CAN BE EXPRESSED UNIFORMLY IN TERMS OF THESE IMPORTANT FEATURE

- Completeness
- Consistency
- Correctness
- Accessibility
- Security
- Privacy
- Authenticity
- Objectivity
- Transparency
- Reliability

IMPROVING THE HEALTH OF ENVIRONMENTAL MONITORING WHEN USING EPA TEST METHODS

Houck, Ronald – Pennsylvania DEP; Parr, Jerry – Catalyst Information Resources; Schrenkel, Carol – Lionville Laboratory, Inc.

Most environmental analyses performed in the US are done using one of the more than 750 test methods published by the US Environmental Protection Agency (EPA) that were developed for trace environmental analyses. An indication of the health of the industry would be to compare the expected performance of these methods to what would be considered a reasonable measure of accuracy. For trace environmental analyses, a measure of good performance is considered to be within 70 to 130 % of the true concentration. Using this measure, many published EPA methods cannot be considered to be healthy. For example, a frequently used method is Method 625, for the determination of semivolatile organics. Of the 64 analytes listed in this method, a recovery of 0% is acceptable for one third of the analytes while a recovery of less than 70% is acceptable for every analyte. To compound this problem, many of these methods were developed many years ago and since that time, new contaminants of concern have been identified. As the methods have not been updated to reflect the additional of new analytes of concern, laboratories are free to use any performance to demonstrate that a method is appropriate.

The accreditation standard developed by the National Environmental Laboratory Accreditation Conference (NELAC) in 2003 has attempted to address this widespread issue by requiring laboratories to demonstrate performance with a method prior to its use and then on an on-going basis continually demonstrate that the method is being used correctly. However, the NELAC standard also allows a 0% recovery to be considered acceptable. In the NELAC program, laboratories are also required to analyze proficiency test (PT) samples. These results are evaluated using well-defined and established criteria, and for many analytes, the acceptance criteria are comparable to those published in EPA methods with the condition that at least a 10% recovery is required. However, the current NELAC PT program cannot always be used to indicate performance because analytes routinely measured in environmental samples are not required to be measured in PT samples. The NELAC program has also compounded this problem in that some state agencies only accredit for analytes listed within a given published method.

A new approach is needed that will ensure that environmental data generated using any test method not only is of "known quality," but that the quality meets a pre-defined level of performance. This presentation will describe some of the problems with the current prescriptive approach in the use of test methods, highlights some of the compounding issues contained in the 2003 NELAC standard, and present some options for a different approach.

Improving the Health of Environmental Monitoring When Using EPA Test Methods

Or All Is Not As It Seems...

Carol Schrenkel, Lionville Laboratory, Inc. Jerry Parr, Catalyst Information Resources Steve Arms, Florida Department of Health

Assumptions in the Prescriptive Method Approach

The methods have been validated and provide acceptable performance

- Laboratory quality control samples monitor the results to ensure acceptable data is being generated
- Laboratory accreditation programs provide an independent check, through PT samples and review of data

Reality 1

Many EPA methods have not been thoroughly validated and/or do not provide acceptable performance

Method Validation

If a method indicates an analyte can be determined, experimental data exists to support this statement

LOD, LOQ, Precision & Bias, Selectivity (NELAC)

Method 8270

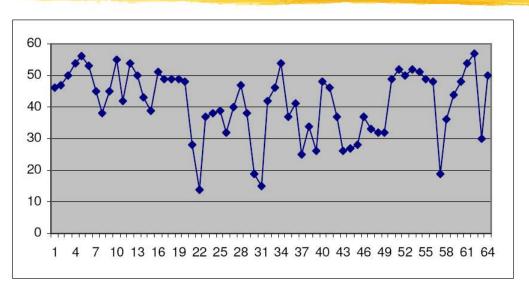

> 240 Analytes
"can be determined"
> 136 with footnotes for Method 3520
e.g., ND = Not determined
> 64 Analytes with interlaboratory performance data (DOD)
> 3 "poor performers"
> 4 "insufficient data"

Acceptable Performance

Mean Recovery of 65-70%
 Mean RSD of 30-35%
 Reason:

 mean - (2 * SD) = lower QC limit (95% confidence)
 65 - (2 * 35) < 0

Method 8270 Provides Unacceptable Performance for Every Analyte

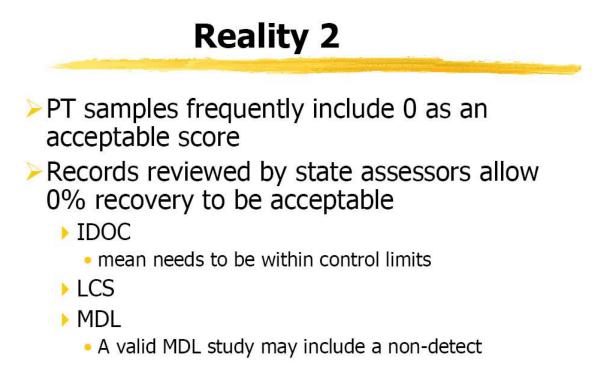

Lower LCS Limits Developed by DOD for Analytes in Method 8270

Method 625 Provides Unacceptable Performance for Every Analyte

Lower Acceptance Limits for Analytes in Method 625

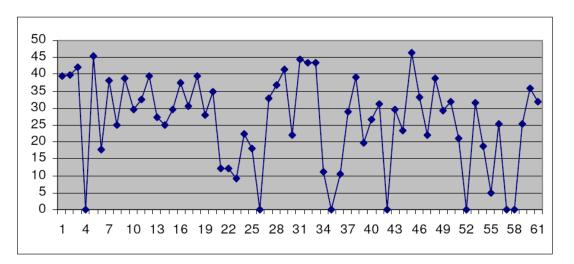

Reality 3

- PT samples do not contain all analytes routinely measured in environmental samples
- A typical BNA PT sample contains 61 Base-Neutrals, 20 Acids
- > 19 analytes have not been included since 2001
- Another 10 include 0 as acceptable when they are included

Reality 3 (cont'd)

40 CFR Part 264 Appendix IX contains 126 semivolatile analytes
45 are not included in the NELAC Fields of Proficiency Testing (FOPT)
29 are not included in PT samples or include 0 in the acceptable range
59% of Appendix IX semivolatile analytes have no performance data

Many Proficiency Test Samples Have Little Value

Acceptable PT Results for Semivolatiles in Water (100 ug/L)

Potential Method Performance (or lack thereof?)

>0 % recovery is acceptable for LCS

- >0 % recovery is acceptable for IDOC
- >0 % recovery is acceptable for MDL study
- >0 % recovery is acceptable for PT samples

WHY BOTHER TO RUN THE SAMPLES??

A Case in Point: 1,4-Dioxane

- Listed in Method 8260 with footnote indicating poor purging efficiency
 - No performance data with Method 5030
- Listed in CLP SOW volatiles
 - Notice given of poor performance
- > Not listed in Method 8270
 - 8270 might be a better method unless 8260 is modified
- Not contained in NELAC FOPT
- Recent analyte of concern

Method Performance for 1,4-Dioxane

Neither Method 8260 or 8270 is sensitive enough without modification (FL Groundwater Cleanup Target Level=3.2 ug/L)

- Method 8260, heated purge and trap, SIM
 - Recovery acceptance limits, 70 130%
 - RPD limit, 20%
- Method 8270, optimized for 1,4-Dioxane
 - Recovery acceptance limits, 10 150%
 - RPD limit, 50%
- > Method 8270, Isotope Dilution
 - Recovery acceptance limits, 15 110%
 - RPD limit, 30%

Data from field comparison study report, conducted by BBL Environmental Services, Inc. on behalf of Lockheed Martin in May 2006

Accreditation for 1,4-Dioxane

Laboratory cannot be accredited for this analyte using Method 8260 (method must be modified beyond what is acceptable for accreditation)

 Ironically, a lab could be accredited by 8260 <u>without</u> the needed modifications

Laboratory cannot be accredited for this analyte using Method 8270 (analyte not listed)

Florida Laboratories

>41 labs with 48 accreditations to analyze for 1,4-Dioxane in non-potable water

- 36 Method 8260
- 3 Method 8015
- 1 CLP Volatiles
- 8 Laboratory SOP
 - 7 based on 8270
 - 1 based on 8260

Time for A Change Educate Data Users

- MQOs/DQOs should be set prior to sampling
- There are method limitations and tradeoffs between # of analytes and cost
- A large # of analytes may be determined by a method, but it was not intended that all could be measured in the same sample and achieve reliable data across the board

- Accredit these analytes by method within the laboratory's Quality System and demonstrated capability of the method
 - Recognizing that data will be within method limitations (and continue to include 0!), OR
- Accredit only a specific list of analytes for which performance data exists (e.g., FOPT), BUT
- Accredit uniformly nationwide to prevent possible unintended competitive advantages

Time for A Change

- Allow labs to use any method that gets reliable data
- > Do not accept 0% recovery
 - Remove the analyte or modify the method
- Accredit labs based on SOP and not on a method which may or may not be appropriate

THE GOOD, THE BAD AND THE UGLY REVISITED ENVIRONMENTAL TESTING IN THE 21ST CENTURY

Burrows, Richard; Severn Trent Laboratories

At this meeting in 1998, I presented a paper, *The Good, The Bad and The Ugly*, discussing prescriptive vs. performance based methods. This paper will examine progress made since then, examining the causes of some problems in environmental testing and possible solutions:

- Barriers to a performance approach
- Controlling data quality
- Problems with the prescriptive approach
- · Widely used performance measures that are bad, or even ugly
- What should a performance approach look like?
- When are prescriptive requirements required?

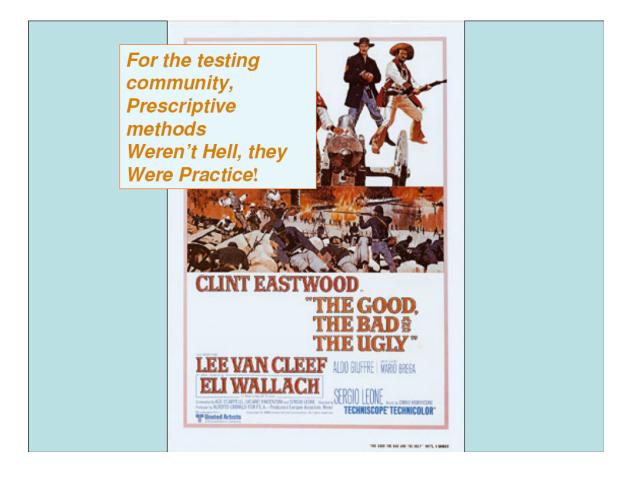

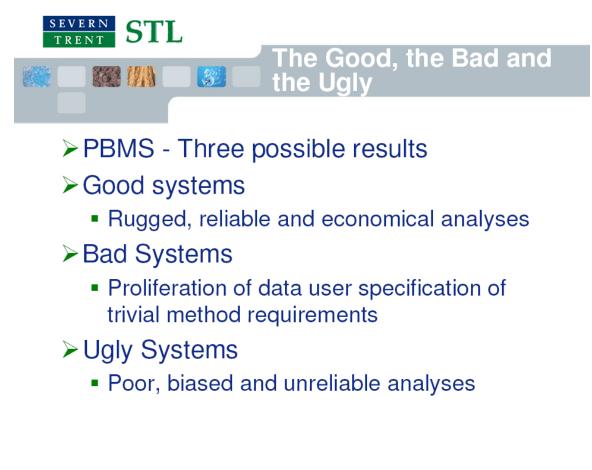

The Good, The Bad and The Ugly Revisited

Richard Burrows

NEMC 2006

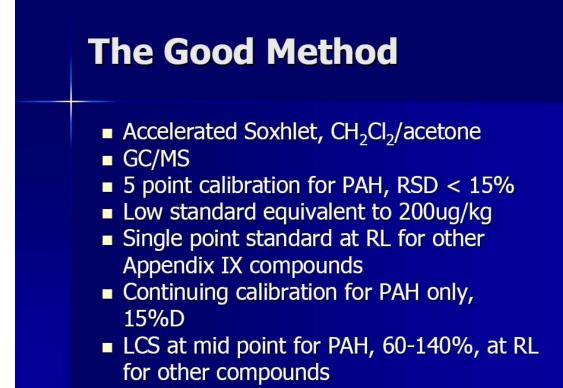

≻ How's it going...

1998 hypothetical

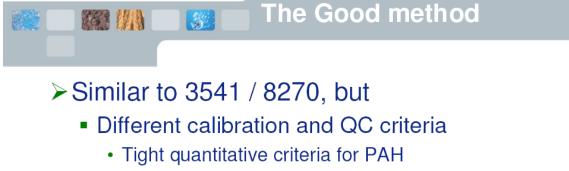

Site investigation

- PAH known to be present
- Other toxic compounds possibly present
- Cleanup goal 500ug/kg for PAH

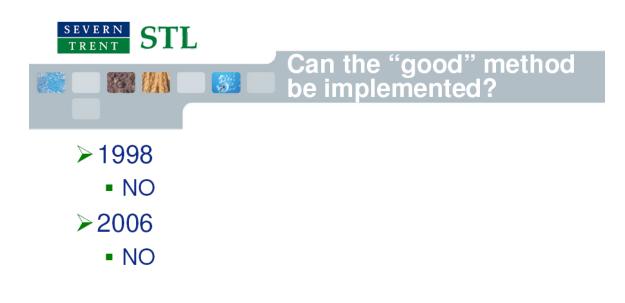

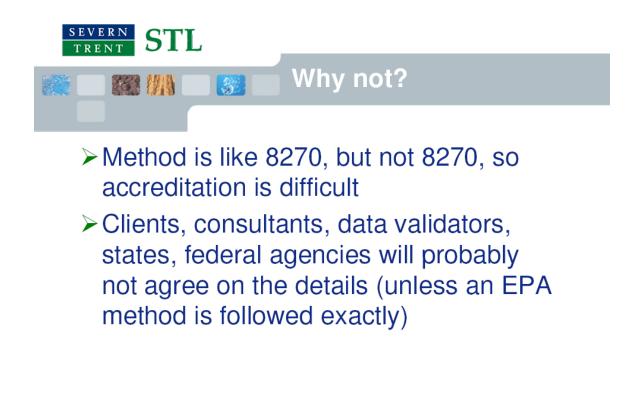

MS/MSD is PAH mix

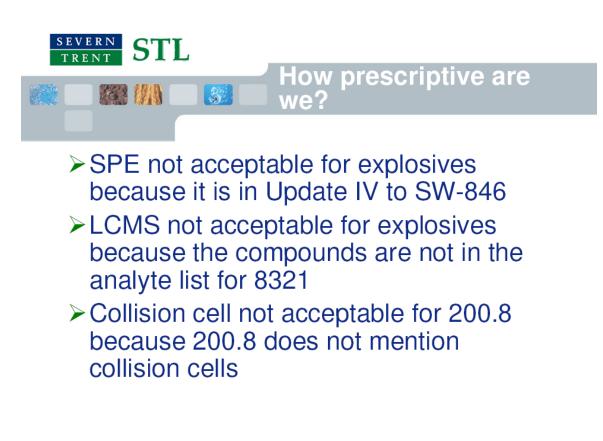

- Detect / non detect for other compounds
- QC focused on analytes of most interest

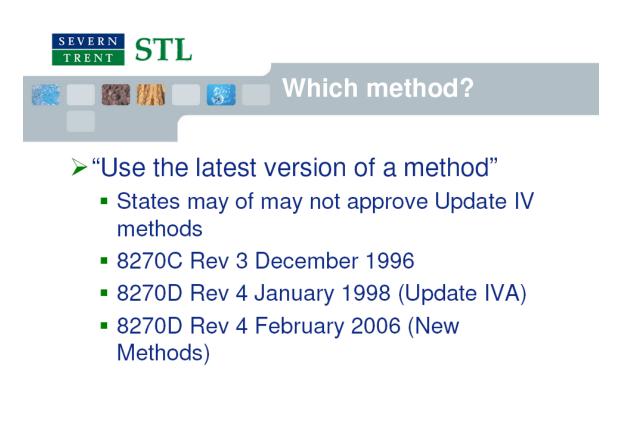

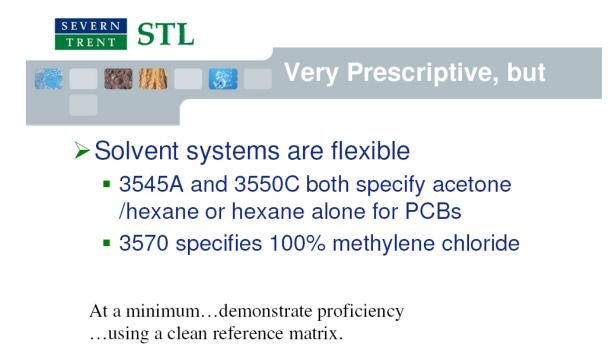

STERE STERE
Is prescriptive OK?
Current system makes sense if
EPA is best at writing methods
EPA can promulgate or make methods available for use in a timely and effective manner
The first is debatable. There are definite issues with the second

Don't trust the labs

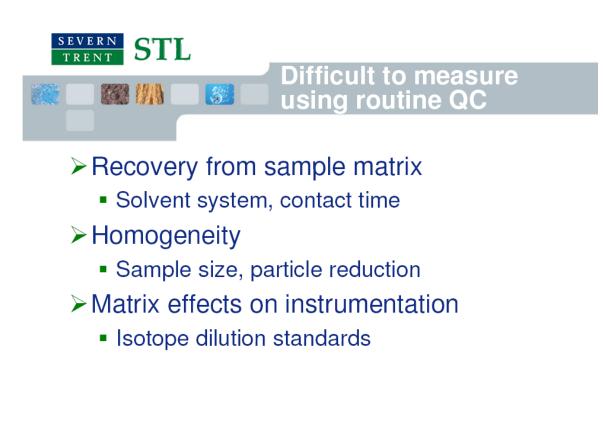

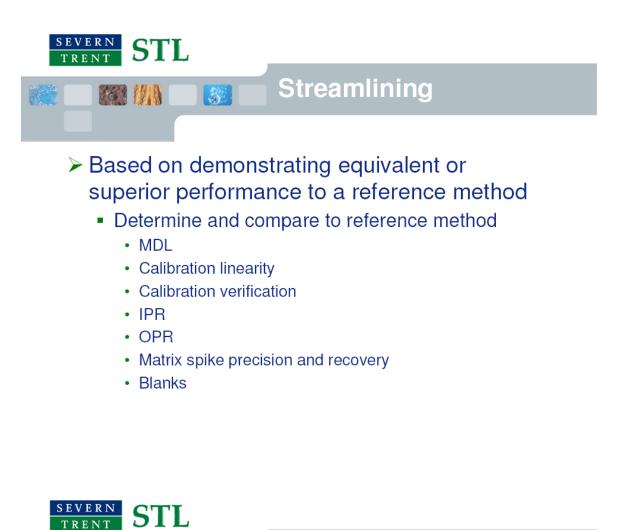

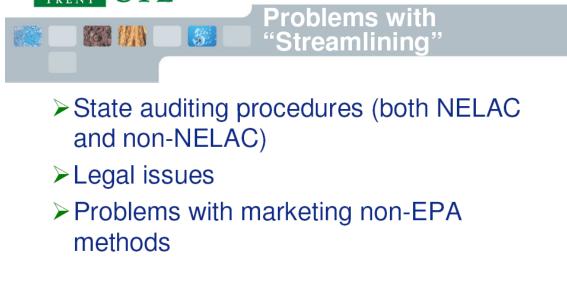

- Use QC criteria where these provide a good measure of performance
- Use prescriptive method details where measurement of method performance using routine QC measures is difficult

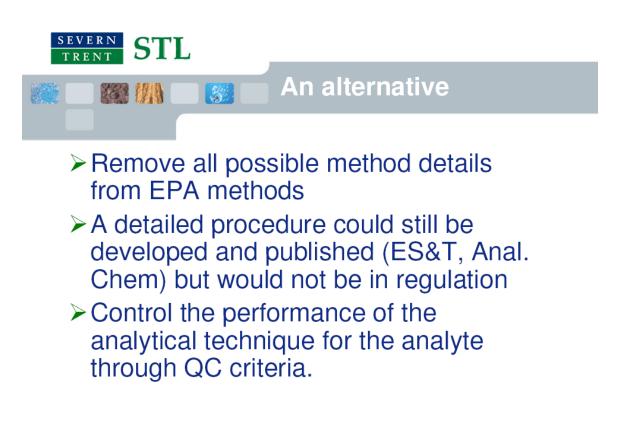

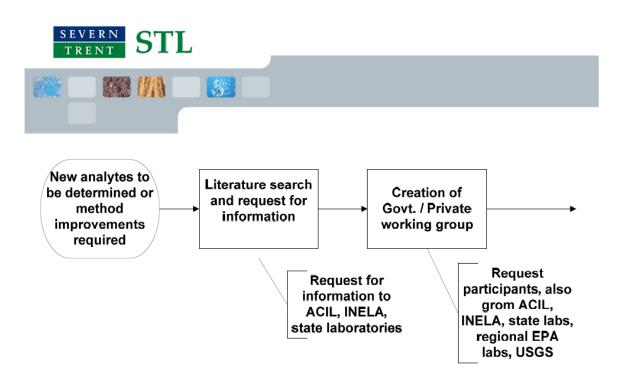

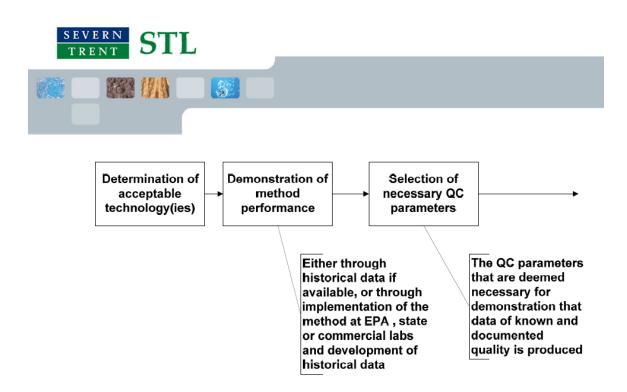

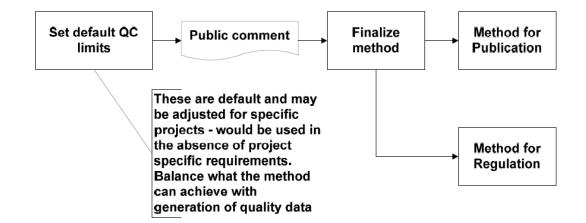

"SW-846 is not intended to be an analytical training manual. Therefore, method procedures are written based on the assumption that they will be performed by analysts who are formally trained in at least the basic principles of chemical analysis and in the use of the subject technology."

- It is very difficult to convert a DQO into a MQO, because the MQO needed depends on how far from a regulatory limit the results are.
- After the fact, we can decide whether the data was sufficient to make a decision, but before the fact we can't say what quality is going to be necessary
- Default criteria are needed

EPA has developed 5 new methods for perchlorate, all have some prescriptive details and are not consistent with each other.

➤Total 169 pages – one analyte

 Not currently useable for compliance monitoring

SEVERN STL

Perchlorate is determined by LC/MS/MS or IC/MS/MS. Mass 83 is used for quantitation and mass 85 for confirmation. In the absence of interferences, single stage mass spectrometry may be used, in which case use mass 99 for quantitation and 101 for confirmation.

method

PBMS perchlorate

¹⁸O labeled perchlorate is used as an internal standard. Aqueous samples may be analyzed directly or following clean up on solid phase columns. Solid samples are extracted using an aqueous leach. Identification of perchlorate requires peaks for the quantitation and qualifier ions to maximize within one scan, and within 0.1 minutes of the labeled perchlorate internal standard.

In the absence of project specific quality control requirements the following must be used:

PERFORMANCE BASED MEASUREMENT SYSTEMS

Blye CEAC, David R.; Environmental Standards, Inc. Vitale CEAC, CPC, Rock J.; Environmental Standards, Inc.

Performance-Based Measurement Systems (PBMS) is an excellent tool by which analytical buyers can develop new or modify existing analytical methods to meet project-specific objectives. Conversely, PBMS has been inappropriately construed as a license to modify existing methods in a manner that enhances laboratory sample through-put, without necessarily generating high-quality analytical data. The proper use of PBMS for the purpose of generating high-quality analytical data requires the buyers of analytical services to be educated in terms of getting generically written methods to "work" for their program and compounds of interest. Unfortunately, the lion's share of analytical buyers are uneducated in terms of purchasing analytical services and tend to purchase services based solely on cost. Because cost is often the overriding factor, some commercial laboratories' offerings, under the misapplied auspices of PBMS, are less desirable in terms of generating an accurate analytical result. This presentation will present "how to do it right."

Performance-Based Measurement Systems A Double Edged Sword Buyer Beware

> 22nd Annual NEMC August 31, 2006

David R. Blye, CEAC Rock J. Vitale, CEAC, CPC Environmental Standards, Inc.

Topics

- PBMS and MIR revisited
- The Double Edged
 Sword
- Doing it Right!

PBMS and MIR Revisited

- PBMS conveys "what" needs to be accomplished, but not prescriptively "how" to do it.
- PBMS is a set of processes wherein the data needs, mandates, or limitations of a program or project are specified, and serve as criteria for selecting appropriate methods to meet those needs in a cost-effective manner. (www.epa.gov/epaoswer/hazwaste/test/pbms. htm)
- HUH?

PBMS and MIR Revisited

- PBMS allows the stakeholders to define what the quantitative MQOs are and provides the flexibility in developing or modifying an analytical method to achieve the criteria.
- Methods Innovation Rule (MIR) allows the use of other practical test methods other than SW-846 for RCRA regulations with exception of the "method-defined parameters" (ex., TCLP)
- PBMS and MIR an opportunity for advancement (?)

PBMS should be good – right?

- One size fits all.
- Take advantage of technology
 - LC/MS
 - LC/MS/MS
 - IC/MS
- Modify existing methods or develop new methods to improve data quality.
- Potentially reduce costs for the lab and customer by matching a method to a particular data use (ex., screening for presence or absence).

The Double Edge Sword

- PBMS *is* good for those reasons, but...CONCERNS
- Can EPA mandate PBMS to compel industry to develop a procedure to look for new Compounds of Emerging Concern (CECs) or a ridiculous sensitivity level?
- Will labs on the DARK SIDE use PBMS as a license to take short-cuts to undercut an already commodity-perceived commercial marketplace?
- Do method modifications truly yield quality enhancements? Clearly some do, but can "modifications" being hidden short-cuts?

The Double Edge Sword

Concerns:

- Comparability of results generated by varying PBMS-developed techniques? Ours vs. Theirs.
 - Qualitative or quantitative impacts of technique used.
- How can we expect PBMS to take hold when we can't even have a soil VOC method proven to be scientifically better (5035) universally accepted in the industry and mandated by regulators?

The Double Edge Sword

Concerns:

- Analytical buyers are (unfortunately) generally uneducated and don't know the differences, pit-falls, gaps and limitations with SW-846 methods as they are written. How can we expect them to *get* PBMS?
- Uneducated regulators; knowledgeable individuals in analytical issues at the project level where decisions are made are lacking.

The Double Edge Sword

Concerns:

- Lack of competent analysts in the commercial laboratories.
 - Many are not chemists
 - Poor understanding of analytical chemistry concepts – calibration techniques, quality control data interpretation etc.
 - Unfamiliar with nomenclature, compound structure and the chemistry behind the current methods.

The Double Edge Sword

Concerns:

- Is there is a viable commercial market for enhanced analytical offerings given COST is the current driver.
- Cost involved in developing and validating new project-specific methods.
- Its easy to hide behind EPA "approved" methods. PBMS can be scary.

Doing it Right!

- The monitoring and analytical community MUST promote EDUCATION of the Stakeholders.
 - Regulated
 - Regulators
 - Lab Community
- · Analytical chemistry "short courses."
- Quality Control concepts.
- With some fundamental concepts, stakeholders can begin to use PBMS to their benefit.

11

Doing it Right!

- First, method selection is driven by DQOs.
- Does an existing, approved method meet your needs?
- IF NOT, then we consider modification or method development.
- Engage a competent laboratory EARLY in the process.
 - Laboratories with strong technical expertise and that place an emphasize on methods development will embrace PBMS.
- Engage a competent chemistry consultant EARLY in the process.
- Include the regulatory authority in the thought and development process – buy in and concensus.

Doing it Right!

Method Modification can be simple! Example - Purge and Trap Method 8260B for tert-butyl alcohol (TBA) consistently caused "rejection" of data due to a RRF < 0.05 (a stupid validation rule in itself).

- d10-TBA Internal Standard was used for quantitation of native TBA. RRF ~ 1.
- Demonstrate, validate and document.

Doing it Right!

- A PBMS thought related to detection and quantitation:
- Instead of MDL reporting, there should be more emphasis on modifying the calibration range and sensitivity of the method to encompass the concentration of concern.

Doing it Right!

Method Development

- Clearly define your Method Quality Objectives (MQOs) to satisfy DQOs.
 - Precision
 - Accuracy
 - Sensitivity
- Research and understand the nature of the compound(s) of concern.
- Will one or multiple techniques be necessary?

Doing it Right!

- Develop and "experiment" with the proposed techniques.
- Test robustness.
- · Evaluate selectivity.
- Evaluate potential interferences.
- Refine and document the method (SOP).
- Validate the method.

Doing it Right!

Method Validation

- Provide objective evidence that the MQOs are achieved.
- Should be as rigorous as necessary for the application (presence/absence vs monitoring at the MCL.)
- MDL and QL determination and confirmation
- Precision and Accuracy/Bias spikes, spike replicates.

17

Summary

- Promote education in PBMS use and concepts.
- Buyer beware. Include technical specifications for all work, even for approved methods.
- Project Teams must account for the time it takes to modify or develop methods in project schedules.
- Labs must insist on a more active role in the project for PBMS to be successful.

DEVELOPMENT OF NEW EPA PROMULGATED METHODS

Later, Douglas W.; Dionex Corporation Munch, David J.; U.S. Environmental Protection Agency

The timely development of new EPA-promulgated methods that are inclusive of the latest technology is of prime interest to all stakeholders in the environmental community, including regulators that develop, promulgate, and enforce use of methods, suppliers that develop and provide analytical instrumentation for performance of methods, and laboratories that are ultimately responsible for using the methods to generate and report scientifically valid and legally defensible data. In the past, there has been much criticism and debate about the difficulty of developing new methods based on state-of-the-art analytical technologies. Timely promulgation of new environmental testing methods has also been a high-energy focal point. Performance-based methods have been advocated by some as the means to address these problems. There is, however, much debate within EPA and the stakeholder community on an appropriate performance-based implementation process that provides flexibility in the development of analytical methods without compromising the integrity of quantification and numeration principles as intended using the traditional reference method approach.

In this paper, a truly functional collaboration paradigm that has evolved over the past few years between Dionex as a supplier and the EPA Office of Ground Water and Drinking Water, Technical Support Center (EPA-OGWDW-TSC) will be described. This collaboration paradigm has been effective in the development of several new methods for drinking water analysis. For example, our two organizations have worked effectively to develop and promulgate two new methods for bromate analysis (Methods 317.0 and 326.0), which have recently been promulgated as part of the Phase II Drinking Water Regulations. Furthermore, 3 new methods have been collaboratively developed for the determination of low-level perchlorate (Methods 314.1, 331.0, and 332.0) and have been proposed as part of the UCMR II Rule (August 2005). Continuing, a new method for the analysis of cations (ASTM 6919) in drinking water has been proposed in the Analytical Methods Update Rule form the Office of Water (April 2004). Currently, EPA-OGWDW-TSC and Dionex are collaborating on the development of many other new methods for the analysis of bromate, perchlorate, oxyhalides, haloacetic acids, paraquat-diquat, and other emerging environmental contaminants using the most recent analytical technologies such as twodimensional chromatography, IC, LC, IC-MS, IC-MS/MS, LC-MS and LC-MS/MS. This collaboration has also reached out to the testing laboratory community to involve them in the generation of method validation data. In this collaborative manner between agency-supplierlaboratory, new methods that include the latest analytical technology are finding there way into use in a much more timely manner. This paper is intended to present and promote this type of collaboration paradigm in the environmental community.

A Collaborative Approach to the Timely Development of New EPA Promulgated Methods for Emerging Environmental Contaminants

Douglas W. Later, Dionex Corporation David J. Munch, EPA Office of Ground Water & Drinking Water, Technical Support Center

The 22nd Annual National Environmental Monitoring Conference Arlington, Virginia August 28—31, 2006

The 'Dilemma'

- New technology for detection and quantitation of emerging environmental contaminants can quickly outdate traditional reference methods.
- EPA Offices are continually working to keep pace with emerging technologies and new environmental contaminants to keep methods current and publishedpromulgated in a timely manner.
- High data quality consistent with DQOs must to be available for making scientifically sound regulatory decisions.

The 'Stakeholders'

U.S. EPA Offices

- Method Developers and Promulgators
- Regulators
- Enforcement Branches
- Technology Innovators
 - Instrument Companies
 - University and Research Institutes
 - Suppliers
- Testing Laboratories- Users of the Methods
- Customers- Reviewers and Users of the Data

The 'Options'	
 Develop Methods in Isolation – can be slow and not acceptable to most stakeholders – may not use the latest technologies 	
 Performance-Based Measurement Systems (PBMS) too flexible for some, but not all, stakeholders data quality is heavily dependent on competence of users dependent on available resources that can be committed to me development 	ethod
 permits method development by laboratories that do not have a resources nor expertise 	adequate
 3rd-Party Standard Setting Organizations (e.g. ASTM) acceptable to many stakeholders, but can still be slow data quality can be variable and dependent on application 	
 Collaboratively-Developed Reference Methods (CDRM) improvement in speed of methods development and timely pub provides excellent approach combining experienced method development swith the latest technology and technological experts another method development approach – not a panacea 	

The 'Key Concerns'

 Flexibility in analytical method development without compromising the integrity of quantitation and numeration principals of traditional reference methods

Resources

- Funding
 - Time
 - Staff
- Expertise
- Technology

Relationship Balance

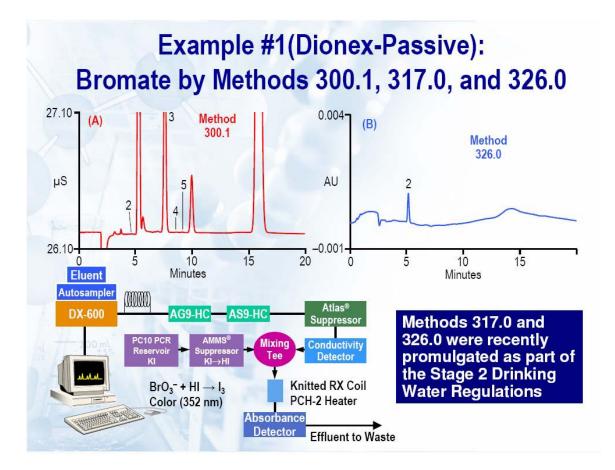

- The agency must maintain a position of neutrality and 'nonendorsement'
- The commercial method co-developers must not 'over-exploit' their position

Summary of Recently Developed and In-Progress CDRMs

- Methods Developed and Proposed or Promulgated
 - Method 317.0: Bromate by IC-PCR (ODA method)
 - Method 326.0: Bromate by IC-PCR (HI method)
 - ASTM Method D 6919-03: Cations by IC
 - Method 314.1: Perchlorate by Suppressed Conductivity Detection with Cryptand Concentrator
 - Method 331.0: Perchlorate by LC-MS/MS
 - Method 332.0: Perchlorate by IC-MS and IC-MS/MS
- Methods Currently in Development
 - Method 314.2: Perchlorate by Suppressed Conductivity Detection using 2-D IC
 - Bromate by Suppressed Conductivity Detection
 - Paraquat/Diquat by Ion-Pairing LC-MS/MS
 - Haloacetic Acids by IC-MS/MS
 - Oxyhalides by IC-MS

Perchlorate

TWO DIMENSIONAL ION CHROMATOGRAPHIC METHOD

DeBorba, Brian; Dionex Corporation Later, Douglas W.; Dionex Corporation Lin, Rong; Dionex Corporation Pohl, Chris; Dionex Corporation Srinivasan, Kannan; Dionex Corporation

Bromate is presently regulated in drinking water at an MCL of 10 ug/L using EPA Methods 300.1, 317.0 and 326.0. Perchlorate has been proposed as an UCMR 2 target analyte to be monitored at 0.5 ug/L using EPA Methods 314.0, 314.1, 331.0, and 332.0. Determining emerging ionic environmental contaminants such as perchlorate and bromate at parts-per-billion (ppb) concentrations can be challenging due to other anionic species present in the matrix at high parts-per-million (ppm) level, such as chloride, sulfate, carbonate, etc. The challenge is further magnified by the fact that the matrix ions tend to elute the contaminant ions of interest causing recovery and peak shape anomalies. Suppressed conductivity detection is selective toward ionic species, has adequate sensitivity for detecting trace perchlorate and bromate, offers lower capital cost, and is simple to use in conjunction with an ion chromatographic (IC) instrument. Thus, suppressed conductivity IC is very appealing to many laboratories performing environmental testing. The goal then is to develop a method that eliminates the high concentration matrix anions and minimizes their interferences in the measurement of trace level ionic contaminants.

The objective of this paper is to describe a two-dimensional ion chromatographic (2-D IC) method using suppressed conductivity detection that has recently been developed by this laboratory. A 2-D IC method can be used to provide detection limits for perchlorate and bromate of <1.0 ppb even in the presence of other high-concentration (> 250 ppm) matrix anions, such as chloride, sulfate and carbonate. In the first dimension, up to 4 mL can be injected onto a 4 mm high capacity ion exchange column that is used to separate the contaminant anion of interest from the matrix ions. The contaminant ion is heart-cut using automated valve switching on to a concentrator column while eluting from the first dimension column. In the second dimension, the contaminant ion is further separated on a 1-2 mm microbore anion exchange column. Eluent from the 1st and 2nd dimension separations are suppressed using a self-regenerating suppressor, and the analyte detected and quantified using conductivity detection. The entire 2-D IC system is automated from injection to data reporting under the control of a chromatographic management system (CMS). Separation of the target analyte from the matrix anions in the 1st dimension in conjunction with a sensitivity enhancement that is proportional to the flow rate ratio between the 1st and 2nd dimensions affords detection limits for perchlorate and bromate on the order of 100 parts-per-trillion (ppt). This paper will describe the 2-D IC instrumentation used in these methods, demonstrate method robustness and simplicity, as well as report on data generated for a recently proposed draft EPA Method 314.2 for perchlorate.

A Two-Dimensional Ion Chromatographic Method for the Ultra-low Level Determination of Perchlorate and Bromate Using Suppressed Conductivity Detection

Douglas Later, Rong Lin, Brian DeBorba, Kannan Srinivasan and Chris Pohl

The 22nd Annual National Environmental Monitoring Conference Arlington, Virginia August 28—31, 2006

Presentation Outline

- Background Information on Perchlorate and Bromate
 - Occurrence
 - Health Effects
 - Regulatory Status
 - Current Methodologies
- 2-D Ion Chromatography (IC) Technology
- Perchlorate 2-D IC Application
- Bromate 2-D IC Application
- Summary

Sources of Perchlorate Contamination

- Rocket fuel production and waste disposal
- Munitions and explosives production and waste disposal
- Fireworks production, use and disposal
- Road flare production and disposal
- Hazardous waste disposal sites
- Phosphoric acid added to food and beverage products
- Indiscriminate chemical disposal

22271

Perchlorate Health Issues*

"Perchlorate interferes with the iodide uptake into the thyroid gland."

- Interferes with thyroid hormone production
- Interferes with thyroid regulation of metabolism
- Interferes with neurological development of fetus and newborn
 - Behavior changes
 - Delayed development
 - Decreased learning capability
- Changes in thyroid hormone levels may result in thyroid gland tumor
 - * U.S. EPA website (www.epa.gov)

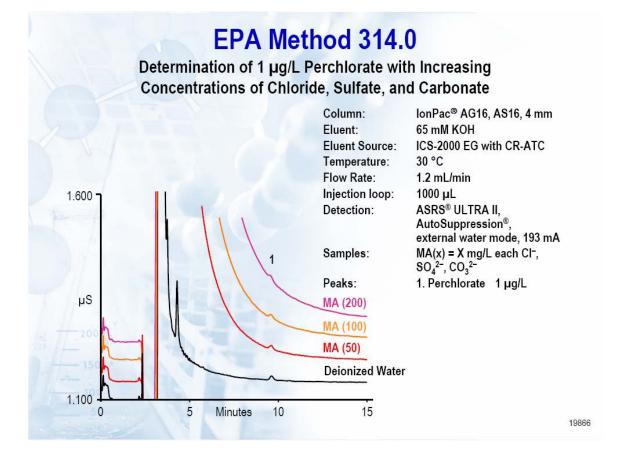

U.S. EPA Unregulated Contaminant Rule (UCMR)

- Initial UCMR (1999) monitoring requirement
 - Required drinking water utilities to monitor and report perchlorate at levels > 4.0 ppb (January 1, 2001 to December 31, 2003)
 - EPA Method 314.0 required for measuring perchlorate
- UCMR II (2007)
 - Will require major water utilities to again monitor and report perchlorate levels in finished drinking water at >0.50 ppb (starts January 1, 2007)
 - Must use one of these EPA methods*:
 - » Method 314.0—IC with Conductivity Detection
 - » Method 314.1—Preconcentration IC with Conductivity Detection and Second Column Confirmation
 - » Method 332.0—IC-MS or IC- MS-MS
 - » Method 331.0—LC-MSMS

Note: Must be able to quantify sub-ppb of perchlorate, even in a matrix with 1000 ppm, each, chloride, bicarbonate, and sulfate

* If Perchlorate > 0.5 ppb, must ensure the value is really Perchlorate by analyzing with a confirmatory method; must demonstrate method used has an LCMRL of < 0.5 ppb</p>

Instrumentation Cost Analysis by Method

Method	Technique	Relative Cost	Cost Range
Method 314.0	IC-CD	+	~\$25 - 50K
Method 314.1	IC-CD-SCC	++	~\$60 - 80K
Method 332.0/6860	IC-MS	+++	~\$150 - 175k
Method 332.0/6860	IC-MS/MS	+++	~\$150 - 175k
Method 6850	LC-MS	++++	~\$150 - 200k
Method 331.0	LC-MS/MS	++++	~\$175 - 225k

Sources of Bromate in Drinking Water

Disinfection Treatment	Disinfection By-Products
Chlorination	Trihalomethanes Haloacetic Acids Chlorate
Chlorine Dioxide	Chlorite Chlorate
Chloramine	Chlorate
Ozonation	Bromate

Toxicology of Bromate

- Clinical signs of bromate poisoning in humans* include:
 - Anemia, hemolysis, renal failure, hearing loss
- Carcinogenicity:
 - Animals: International Agency for Research on Cancer (IARC) has concluded that bromate is carcinogenic in animals
 - Humans: IARC has assigned bromate to Group 2B (the agent is possibly carcinogenic to humans)

*World Health Organization, Geneva, 2000

Regulation of Bromate in Municipal Drinking Water

• 1993

 World Health Organization (WHO) set a guideline of 25 µg/L bromate in drinking water

• 1998

- U.S. Environmental Protection Agency established a 10 µg/L bromate maximum contaminant level (MCL) in drinking water and a maximum contaminant level goal (MCLG) of zero under the Stage 1 disinfectants/ disinfection by-products (D/DBP) rule
- European Union reduced the regulatory value from 50 to 10 µg/L bromate

2003

- WHO set a provisional value of 10 µg/L bromate in drinking water

♦ 2004

- U.S. Environmental Protection Agency, Stage II D/DBP rule leaves MCL at 10 µg/L
 - The U.S. FDA adopted the U.S. EPA's MCL for bromate in bottled waters

New 2-D Method—Features

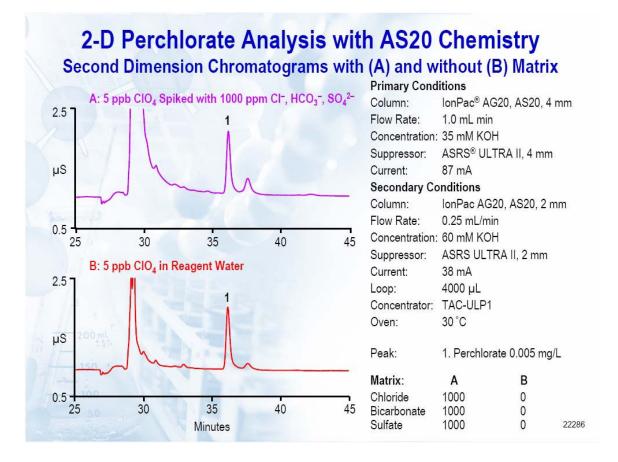

- Allows for large loop injection in the first dimension (4-mm column)
 - Possible to inject a larger loop than the standard approach since the capacity and selectivity of the analytical column in the first dimension dictates the recovery and the analyte of interest is analyzed in the second dimension
- Focus the ions of interest in a concentrator column after suppression in the first dimension
 - Hydroxide eluent suppressed to D.I. water thus providing an ideal environment for focusing or concentrating the ions of interest
- Pursue analysis in the second dimension using a smaller column format operated at a lower flow rate leading to sensitivity enhancement that is proportional to the flow rate ratio
 - For a 4-mm column operated in the first dimension at 1 mL/min and a 2-mm column operated in the second dimension at 0.25 mL/min, the enhancement factor is 4
- Easy implementation on through state-of-the-art IC instrumentation

22489

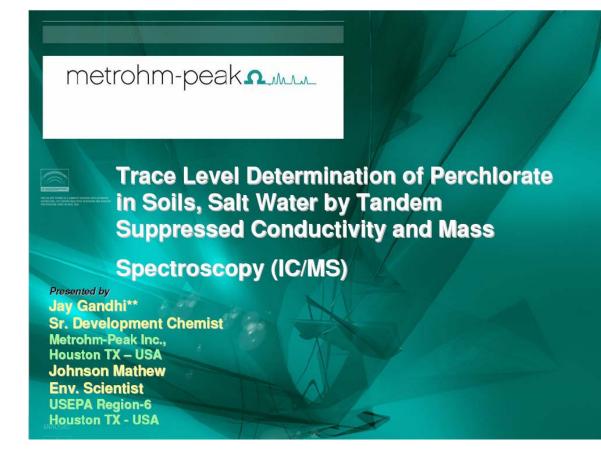

Summary

- Trace analysis of environmental contaminants such as perchlorate and bromate push the performance limits of conventional determinant methods such as IC with suppressed conductivity detection.
- Matrix composition is most frequently a factor in trace analysis.
- Confirmation analysis is required for definitive determinations, which normally requires more sensitive and selective detection and quantitation.
- Matrix elimination techniques assist in reducing interferences and enabling better sensitivity using conventional detectors.
- ◆ 2-D IC is a cost effective technology that allows confirmatory trace analysis using conventional detection.

TRACE LEVEL DETERMINATION OF PERCHLORATE IN SOILS, SALT WATER BY TANDEM SUPPRESSED CONDUCTIVITY AND MASS SPECTROSCOPY (IC/MS)

Gandhi Sr., Jay; Metrohm-Peak, Inc.

Perchlorate salts are being used as rocket propellants, in fireworks and in the electroplating industry. Recently, it is believed by the scientific community that Perchlorate hinders the iodine absorption ability of the thyroid gland posing higher health risk for the public. Perchlorate can be released into the soils, ground water, surface water and irrigational waters, which in turn contaminate crops of vegetables and fruits. It is critical to identify and quantify levels of Perchlorate contamination in soils, saltwater and waste effluents from Perchlorate manufacturing sites. This presentation demonstrates use of conventional ion chromatography conductivity detection and mass spectrometer in tandem. Difficulties and remedies in sample extractions along with benefits of mass spectrometer will be discussed.

22nd Annual National Environmental Monitoring Conference

THE HIGHEST LEVELS OF PERCHLORATE DETECTED IN FOODS AND BEVERAGES BY ION CHROMATOGRAPHY COUPLED WITH TANDEM MASS SPECTROMETRY (IC-ESI-MS/MS)

Antonsen, Stephen – Dionex Corporation; El Aribi, H. – MDS Sciex; Le Blanc, Y. – MDS Sciex; Sakuma, T. – MDS Sciex

A new IC-ESI-MS/MS method, with simple sample preparation procedure, has been developed for quantification and confirmation of perchlorate (ClO_4) anions in water, fresh and canned food, wine and beer samples at low part-per-trillion $(ng 1^{-1})$ levels. To the best of our knowledge, this is the first time an analytical method is used for determination of perchlorate in wine and beer samples.

The IC-ESI-MS/MS instrumentation consisted of an ICS-2500 ion chromatography system coupled to either an API 2000TM or an API 3200TM mass spectrometer. The IC-ESI-MS/MS system was optimized to monitor two pairs of precursor and fragment ion transitions, i.e., multiple reaction monitoring (MRM). All samples had oxygen-18 isotope labeled perchlorate internal standard added prior to extraction. Chlorine isotope ratio $(^{35}C1/^{37}C1)$ was used as a confirmation tool. The transition of $^{35}C1^{16}O_4^-$ (m/z 98.9) into $^{35}C1^{16}O_3^-$ (m/z 82.9) was monitored for quantifying the main analyte; the transition of $^{37}C1^{16}O_4^-$ (m/z 100.9) into $^{37}C1^{16}O_3^-$ (m/z 84.9) was monitored for examining a proper isotopic abundance ratio of $^{35}C1/^{37}C1$; and the transition of $^{35}C1^{18}O_4^-$ (m/z 107.0) into $^{35}C1^{18}O_3^-$ (m/z 89.0) was monitored for quantifying the internal standard. The minimum detection limit (MDL) for this method in de-ionized water is 5 ng 1⁻¹ (ppt) using the API 2000TM mass spectrometer and 0.5 ng 1⁻¹ using the API 3200TM mass spectrometer.

Over 350 food and beverage samples were analyzed mostly in triplicate. Except for four, all samples were found to contain measurable amounts of perchlorate. The levels found ranged from 5 ng Γ^1 to 463.5 ± 6.36 µg kg⁻¹ using MRM 98.9 \rightarrow 82.9 and 100 µl injection.

The Highest Levels of Perchlorate Detected in Foods and Beverages by IC-ESI-MS/MS

LC- or IC- MS/MS Topics in Environmental Analysis

- * Pesticides (target analysis, screening, very polar pesticides)
- Perchlorate
- * Disinfection by-products: haloacetic acids, bromate, trihamethanes, etc...
- * Estrogens and endocrine disruptors
- * Fluorinated compounds
- * Brominated flame retardants
- ✤ Polycyclic aromatic hydrocarbons
- Explosives
- Algal toxins and shellfish toxins
- Biogenic amines
- Antibiotics

They are found in contaminated water, food, beverages, soils, etc... They could pose a serious threat to human health.

- * Screening for emerging compounds, etc....
- 2

LC- or IC-MS/MS Involves...

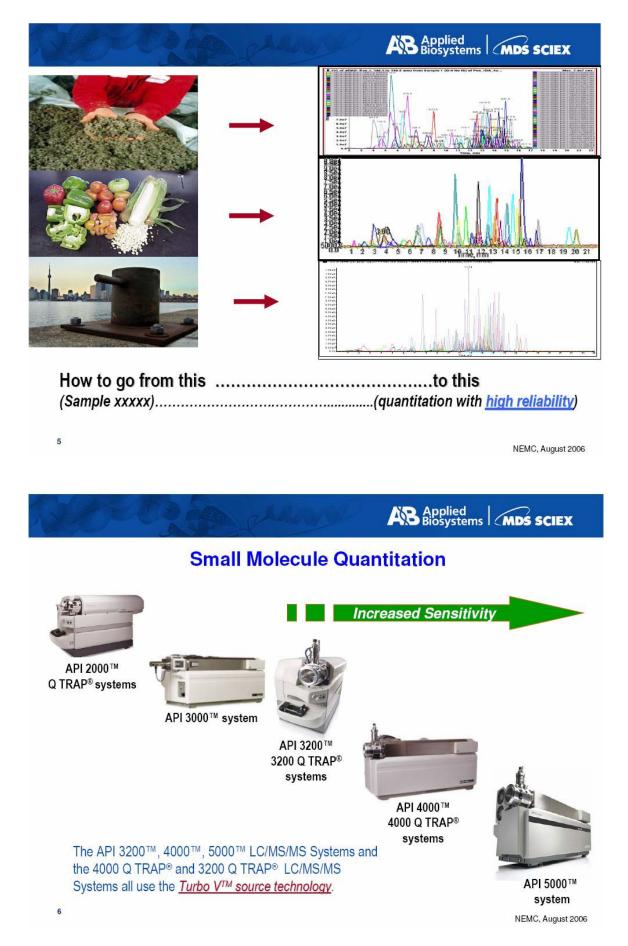

- * Chromatography separation of analytes
 - Pumps
 - Autosampler
 - Column
- Ionization ion production
 - Electrospray (ESI, TurbolonSpray[®] source)
 - Atmospheric Pressure Chemical Ionization (APCI)
 - Atmospheric Pressure Photo Ionization (APPI)
- * MS filtering ion transmission
 - Q1 Selected Ion Monitoring (SIM)
 - Q1-Q3 parent to product ion transitions (MRM); highly specific
 - Other possibilities as well...
- Detection ion detection (signal to peak)
- Data analysis

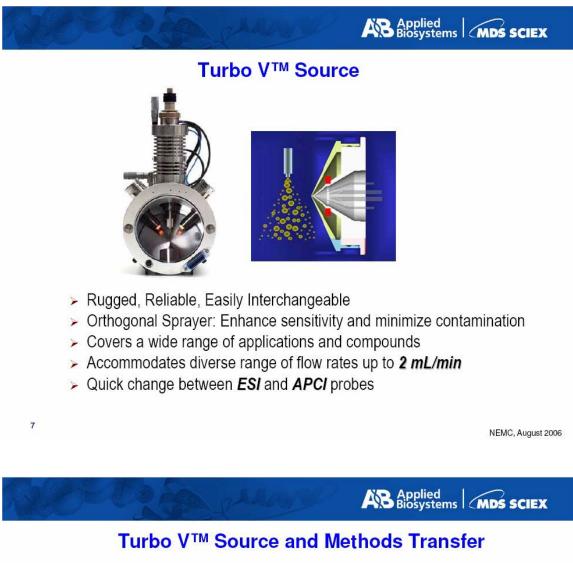

4

- Qualitative (what is it?)
- Quantitative (how much is present?)

Perchlorate

> Perchlorate is a powerful thyroid toxin that can affect the thyroid's ability to take up the essential nutrient iodide and make thyroid hormones and thus affects:

- Thyroid hormone production
- Thyroid regulation of metabolism
- Size of brain structures

nalysis of perchlorate using API 3200™

- Neurological development of fetus and newborn

Small disruptions in thyroid hormone levels <u>during pregnancy</u> can cause lowered IQ and larger disruptions cause mental retardation, loss of hearing and speech, or deficits in motor skills for infants and children.

Thyroid hormones control fetal/infantile neurodevelopment. "<u>Iodine deficiency</u> is the single most important preventable cause for mental retardation".

.....Thyroid hormones regulate metabolism in adults, <u>but</u> pregnant women face a special risk because these hormones help guide the brain and nerve development of their fetuses.

Analysis of perchlorate using API 3200™

Applied Biosystems

Perchlorate Analysis

Perchlorate has received widespread attention as an environmental pollutant. This attention has resulted in development of analytical methods to support its measurement.

Methods 314.1, 331.0, and 332.0.

- Method 314.1 is based on an IC separation preceded by a preconcentration column matrix removal step and followed by suppressed conductivity detection. (EPA approved method for drinking water)
- Method 332.0 relies on an IC separation and suppression of the IC eluent followed by either mass spectrometry (MS) or tandem mass spectrometry (MS/MS) for detection and quantitation.
- Method 331.0 is an LC-MS/MS method that relies on a unique LC column specifically designed for separation of perchlorate using a volatile methylamine-based mobile phase followed by unsuppressed Electrospray Ionization (ESI) MS/MS detection and quantitation.

Isocratic 45 mM KOH

The post column addition of this solvent *improves* the electrospray process and provides a <u>better sensitivity</u> than 100 % water-based run.

AB Applied Biosystems MDS SCIEX

Sample Preparation for Perchlorate Analysis

<u>Water and Urine</u>: Drinking water samples were analyzed without preparation. Waste water and urine samples were filtered.

<u>Fruits and Vegetables</u>: Bulk samples were first cut into small, 1 - 2 cm pieces and chopped in a food processor. Samples were prepared by weighing 10 ± 0.10 g of each food samples into separate 50 mL disposable polypropylene centrifuge tubes. 20 mL De-ionized water was added.

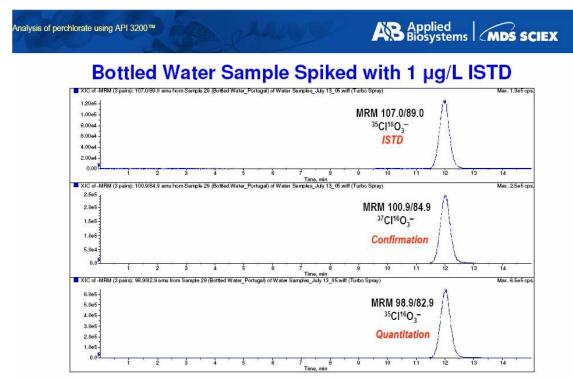

<u>*Milk products*</u>: 5 ± 0.05 mL of each sample was pipetted into separate 50 mL disposable polypropylene centrifuge tubes. 5 mL of de-ionized water and 20 mL of acetonitrile were added.

<u>Wine Samples and other Beverages</u>: Individual sample solutions were prepared by pipetting 5 mL \pm 0.05 mL of each samples into separate 50 mL disposable polypropylene centrifuge tubes. 25 mL of de-ionized water was added.

- The centrifuge tubes were capped and shaken with a Vortex-Genie® for 2 min.
- The tubes containing the test portion were then centrifuged at 2,500 rpm for 25 minutes at room temperature.
- The samples were then filtered with a 0.2-µm pore size nylon-mesh syringe filter.

• All samples have internal standard (18O-labeled perchlorate) added prior to extraction. This effectively corrects for any sample losses during preparation, and for any matrix effects in the ionization process.

alysis of perchlorate using API 3200™

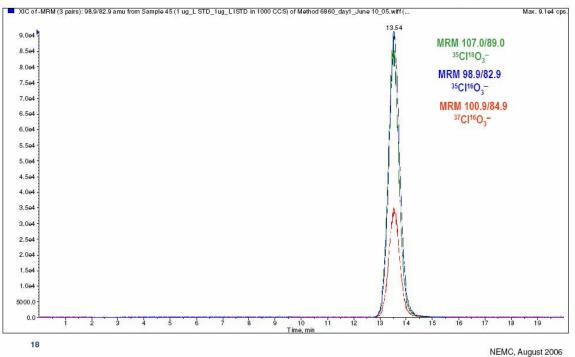

To confirm the presence of perchlorate, the <u>82.9/84.9 peak area</u> count ratio should be between **2.2** and **3.3**. This ratio is derived from the natural abundance of **chlorine-35** and **chlorine-37** isotopes^[1].

RAPID DETERMINATION OF PERCHLORATE ANION IN FOODS AND ENVIRONMENTAL SAMPLES BY ION CHROMATOGRAPHY-TANDEM MASS SPECTROMETRY

Hopper, Marvin L.; Krynitsky, Alexander J.; Niemann, Richard A.; Williams, Anthony D. – U.S. Food and Drug Aministration Center for Food Safety and Applied Nutrition

A rapid, sensitive, and specific method was developed for the determination of perchlorate anion in foods and environmental samples. The foods included fresh fruits and vegetables, whole milk, infant formula, baby foods, grains, and bottled water. The environmental samples included saltwater, soil, and sludge acquired from a recent round robin study conducted by the U.S. Environmental Protection Agency (EPA) Office of Solid Waste. The extraction and cleanup procedures will be discussed for each type of sample matrix and compared to other existing methods. A Waters IC-Pak Anion HR column (4.6 mm x 75 mm) was eluted with 100 mM ammonium acetate in 50:50 (v/v) acetonitrile/water mobile phase at a rate of 0.35 mL/min. A triple stage quadrupole mass spectrometer, equipped with electrospray ionization (ESI) in the negative ion mode, was used to determine perchlorate anion. An ¹⁸O₄-labeled perchlorate anion was used to correct for any matrix effects. Fortified test portions gave recoveries ranging from 80 -120%. Determination of incurred perchlorate anion residues agreed well with results for comparable commodities or products analyzed by published methods.

Potential Food Exposure Pathways

- Crops
 - Irrigation water
 - Soil
- Food-producing animals
 - Water forage feed
- Fish
 - Aquatic environment feed
- Production water containing perchlorate

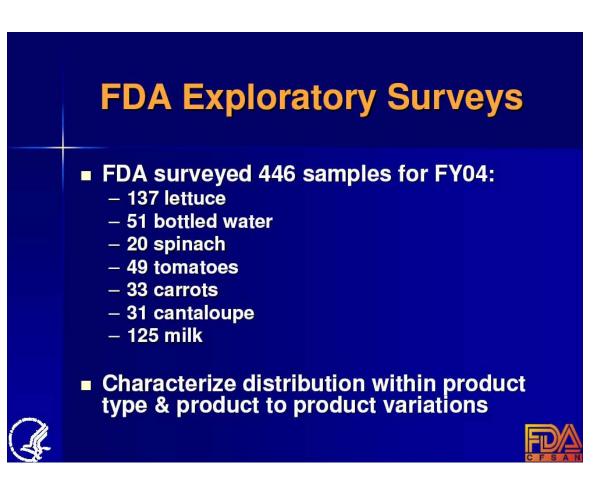

FDA's Strategy and Goals

- Determine the occurrence of perchlorate in a variety of foods.
- Evaluate exposure to perchlorate from food.
- Support any action that might be needed to protect the public health.

- FY 05 perchlorate survey 500 targeted sample (domestic and imports)
- Additional tomato, carrot, spinach, cantaloupe samples.
- Wider variety of food samples:
 - Produce (broccoli, onions, cucumbers, peas, green beans, cabbage, collard greens)
 - Fruit and fruit juices (apple, grape, strawberries, watermelon, apple juice, orange juice)
 - Grain products (rice, wheat flour, corn meal, oat meal)
 - Aquaculture catfish and salmon, and shrimp.

FY05 Activities (cont.)

- Farm milk survey 100 each: raw milk, feed, water.
- Infant formula survey 21 samples.
- FDA's Total Diet Study (TDS) infant foods.
 - 4 market baskets for FY 05.
 - 57 infant foods per market basket.

FY06 Activities

- FY 06 TDS survey about 800 food samples (4 market baskets).
 - Dairy and eggs
 - Meat/poultry/fish
 - Mixtures (e.g., casseroles, sandwiches, soups, pizza) and vegetables.
 - Candy/sweets/ sugars/syrups
 - Beverages
 - 100 targeted follow up and food samples

FDA Analytical Method Development

- IC- electro conductivity detection (less expensive method)
- IC-MS/MS; ESI in negative mode
- Miniaturizing extraction and cleanup procedure for IC-MS/MS to facilitate high sample throughput for a large variety of foods

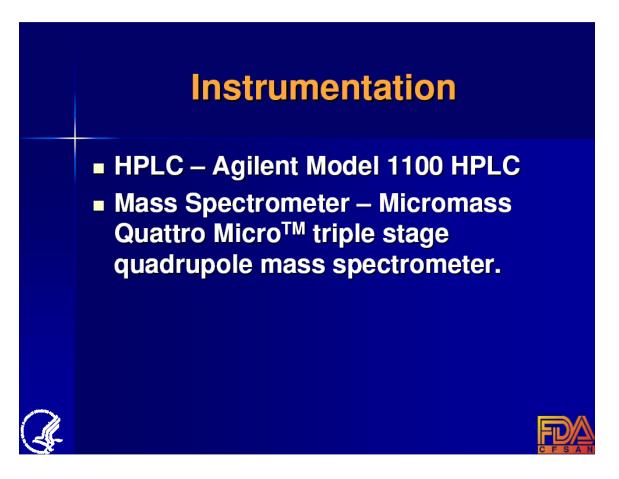

FDA Analytical Method Development

IC-MS/MS

- Anion exchange IC column
- Isotopically labeled internal standard (¹⁸O₄labeled perchlorate)
- 0.5 μg/L LOQ Bottled Water
- 1 μg/kg LOQ Produce, meats, and infant foods
- 3 μg/L LOQ Milk, infant formula
- 3 μg/kg LOQ Low Moisture Foods
- Sample prep extraction/SPE/filtration
- Minimal matrix effects with IS

HPLC Conditions For Perchlorate

- IC Column 4.6 mm x 75 mm Waters IC-Pak[™] Anion HR
- Guard Column Waters IC-PakTM Anion Guard-PakTM
- Mobile Phase 100 mM ammonium acetate in 50:50 (v/v) acetonitrile:water
- Flow Rate 350 μL/min, isocratic
- Injection Volume 50 μL

Advantages To Miniaturization

- Faster than traditional methods
- IS added at beginning, thus more accurate.
- All disposable components
- No need for filtration flasks, etc.
- Comparable results to traditional methods even with "Round Robbins"
- Prep 20 samples in < 2 hr</p>

Precautions with Mini Method

- Use 1% HOAC as Extraction Solution: This is needed to suppress active sites on Envi Carb SPE.
- Use PTFE syringe filters and Not nylon: Perchlorate can be retained on nylon syringe filters.
- Losses of perchlorate are not apparent with matrix since sample matrix will suppress active sites on SPE.

Monitoring ESI Matrix Effects With Labeled IS

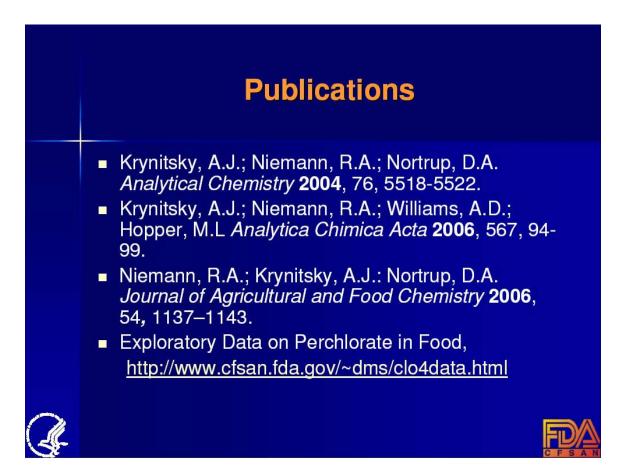

Commodity	Signal Supression/Enhancement
Milk	+20 %
Lettuce	-10 %
Bottled Water	-10 %
Infant Foods	-70 %
Carrots	-10 %
Cantaloupe	-40 %
Spinach	-70 %
Tomatoes	-70 %

Conclusions

- Advantages with IC-MS/MS:
 - Identification and Confirmation
 - Accurate Quantitation
 - Sensitivity and specificity
 - Eliminates False Positives
 - Less sample cleanup needed
- Disadvantage Cost ~ \$230,000
- Must use isotopically labeled IS for accurate quantitation
- Miniaturized Method is versatile for a variety of foods
- FDA has published some of the results from FY 2004 500 sample survey on website: <u>http://www.cfsan.fda.gov/~dms/clo4data.html</u>
- Analytical method available on same website
